

ABSTRACT

A COMPARATIVE ANALYSIS OF THE LITERATURE USED IN PRACTICE COURSES IN SOCIAL WORK AND PSYCHOLOGY

By James Lloyd Richmond

The literature used in casework courses by 29 accredited schools of Social Work and the literature used in psychotherapy courses by departments of Psychology of 28 Universities was compared to determine the extent each discipline drew from the same literature and to examine the nature of existing differences. A questionnaire asking for the names of texts, required readings, and books mentioned on bibliographies was used to secure the information.

Social casework referred to 401 books and psychology to 220. Fifty-two of the books (13%) were mentioned by both disciplines but the coefficient of correlation based on the extensiveness that each book was used by each discipline was only .07. Many books that were referred to frequently by one discipline were only mentioned once by the other discipline.

Psychology had more agreement within its own discipline concerning reference books than was found in social work. Of 220 books included in the psychology department bibliographies, 62 references (28%) were mentioned by only one school, whereas of the 401 reported references by social work, 210 (52%) were mentioned by only one school.

Social casework bibliographies tend to emphasize theoretical content in contrast to psychology which emphasized case

management patterns.

When the theoretical orientation of the departments of social casework and psychology was compared, a wider range of theoretical orientations regarding personality development was found in psychology than was found in the range of social casework reference material. Social work used Freudian oriented authors 44% whereas psychology used Freudian authors 31%. Psychology used non-Freudian authors 25% and social work used them only 11%. The remainder of the books were classified neo-Freudian or eclectic - social work 45% and psychology 44%.

By examining the course outlines that were submitted and the content of books mentioned it was found that psychology offered a greater variety of theoretical approaches to therapy than did social work, most schools covering 5 or 6 approaches such as the Psychoanalytic approach, Client-centered approach, Learning theory approach, the Existential approach, the Rankian and Adlerian approaches, and the Interpersonal school of Sullivan and his followers.

In reviewing the reference material reported by the two disciplines there appears to be some subject matter that is unique to social casework, some that is unique to psychology and some that appears to be of interest to both. Examples of subject matter unique to social casework are the following: agency functioning, recording, eligibility and intake, medical care, use of community resources, home visits, problems of aging, supervision, recriation and modification of the environment. Examples of subject matter apparently unique to psychology are the following: group psychotherapy, psycho-

therapy with children, free association, hypnosis, dream interpretation, psychological testing and research.

Examples of subject matter, however, in which both disciplines have a common interest, as reflected by the frequency of its occurrence in reference material, appear to be the following: short term therapies with the aim of improving the social or interpersonal functioning, emphasizing areas of the clients' current malfunctioning rather than direct exploration of unconscious conflict or repressed infantile memories, greater activity of the therapist, emphasizing the worker-client relationship as a therapeutic tool, discussion concerning transference and countertransference, problems of handling resistive clients, diagnostic formulations, ethics and values in psychotherapy, and prediction of outcome.

Although casework courses cover a greater range of subject matter than do psychotherapy courses, most of what is taught in psychotherapy courses logically fits within the context of the goals and purposes of casework. In fact, many of the authors expressly state that they had psychiatric social workers in mind when they wrote the book as well as psychiatrists and clinical psychologists. It was therefore concluded that social caseworkers were ignoring a wealth of literature which was found to be highly relevant and potentially useful for communicating the skills, techniques and understanding used in therapeutic interviewing.

A COMPARATIVE ANALYSIS OF THE LITERATURE
USED IN PRACTICE COURSES
IN SOCIAL WORK AND PSYCHOLOGY

ACKNOWLEDGMENTS

Although the writer assumes full responsibility for the contents of this study, indebtedness is acknowledged to my faculty adviser, Dr. Max Bruck, who gave editorial assistance and whose enthusiasm for the subject generated interest; to Mr. Arnold Curin, Research Chairman, for his assistance in methodology and statistical analysis; and to Dr. Gordon Aldridge, who graciously composed a forwarding letter for the questionnaires and made editorial suggestions.

Mr. Earl Maillen generously granted permission to duplicate his questionnaire. Mr. Edwin Collins, a psychologist at Pontiac State Hospital, generously offered methodological and editorial suggestions.

Appreciation for their assistance in making classification decisions for some of the books is extended to Dr. Terry Allen and Dr. Jerold King from the Michigan State psychology department. Thanks is also extended to Dr. Frank Restle, Associate Professor of psychology at Michigan State for his methodological suggestions.

The above acknowledgments should not be construed to imply that each of the above mentioned persons expressed approval for each of the writer's methodological decisions in this study.

Indebtedness is also extended to the Schools of Social Work and Departments of Psychology who responded to the questionnaire, especially many schools who painstakingly reproduced copies of outlines and bibliographies which greatly enhanced the study.

Indebtedness and preparation is especially extended to my wife, Janet, who "spent" many hours preparing and tabulating the returns, as well as typing this paper.

CHAPTER I

Introduction

It is well known that social work has borrowed heavily from the discipline of psychiatry, predominantly orthodox psychoanalysis. It has been the observation of this writer that social work literature reflects little interest or awareness of what the discipline of clinical psychology has to offer. This seems paradoxical because in many ways social work has more in common with applied psychology than it does with psychiatry. Previous studies have determined that social work relies almost exclusively upon psychoanalytic personality theory. It is generally agreed that social work borrows heavily from classical psychoanalytic writers in formulating methods of casework treatment. However, there is great disparity between the methods of classical psychoanalysis and methods which can be used in casework. Therefore, many principles and methods applicable to psychoanalysis are not relevant to casework methods. If psychoanalytic theory is helpful in validating social work's understanding of its clients there still remains the problem of how to apply this knowledge to the range of practice generally thought of as social work. If my understanding of social work literature is correct we have incorporated, quite faithfully, the technique and ability to appraise and diagnose the client's problem - according to psychoanalytic principles and into psychoanalytic terms - but due to the differing functions, circumstances and methods social work is unable to parallel the

psychoanalysts' procedures beyond this point. To carry the paradox further we learn from psychoanalytic theory that behavior is largely governed by unconscious forces. The personality structure is formed by age 5 or 6 and can only be modified by regression through analysis - enabling the patient to re-experience these repressed experiences and reorganize (1) the personality structure. Due to our Freudian orientation, we tend to attribute causes of problems to inadequate personality formation (caused by experiences before age 5 or 6) and naturally feel frustrated in offering help because we are not qualified to pursue psychoanalytic methods beyond diagnosis. We attempt to become reconciled to this frustrating situation by doing what we can. Under very optimal conditions, both in regard to the client and the qualifications and supervision of the worker, we venture closer to the methods of psychoanalysis and use what is known as modifying methods. Here the preconscious material is dealt with and the goal is modifying inappropriate defenses. The caution with which these methods are advocated is reflected by the fact that there is comparatively little discussion in the literature regarding the use of them.

It is in the hope of somehow circumventing this paradox, caused by the disparity between our orientation and reality limitations of casework practice, that an examination of the literature used by the discipline of psychology is motivated. Because psychology has incorporated several

(1) This is admittedly oversimplified for the sake of brevity.

differing theoretical orientations, as has been reported
(2)

elsewhere , it would seem fruitful for social work to compare means and ends with this discipline. It is the position of this writer that because some of the theoretical orientation has been developed within the context of non-medical psychotherapy or counseling, this theory can more readily be translated into methods of practice which are also appropriate to social work and therefore, to some extent, "bridge the gap" discussed above.

The data collected in this study will indicate what literature is used in teaching practice courses in psychology and social work. To the extent the ends are similar in each discipline, the means to these ends should be compared and their estimated effectiveness evaluated.

It was hoped that evaluative research on differing methods reported in the literature could be examined and discussed in this paper, but it was decided that it was beyond the scope of this study.

The general purpose of this study is to broaden social work knowledge in the area of therapy and thereby facilitate the training of students to become competent therapists or caseworkers.

The compilation of the bibliographies used by other schools of social work should be of some value to social casework instructors, irrespective of the comparison with courses in psychology.

(2) See last paragraph page 9.

CHAPTER II

Background of the Study Problem

This study occurs in the theoretical context of the methods of educating and training social casework practitioners.

One concerted effort to analyze and evaluate social work education has been the Curriculum Study by the Council on Social Work Education. The review of the Social Casework report indicated that considerable changes were recommended. The contemplated expansion of social work knowledge seems to be in the direction of sociological concepts. While this is essential, I think we could benefit equally from current psychological knowledge as well. It is undoubtedly easier to add sociological concepts to the existing Freudian framework than to consider incorporating alternative theories. The first represents adding to the status quo, while the second may indicate a change.

Opinions of others concerning the need to expand social work to include knowledge available from the social and behavioral sciences are quoted as follows. Some of the comments evaluate the present scientific status and suggest what need be done to improve social work in this regard. Some of the duplication between writers represents the consensus of opinion of these writers and is therefore included.

Present Status:

Some quotations which are intended to evaluate social work's present status:

Social work practice is now a varying dilution of craft and professional art with traces of scientific intent. (3)

Too many of us tend to overlook, subordinate or even disregard the necessity of examining the rational structure - that is, the logical composition - as well as the empirical content of what we do, why we do it, and with what kind of behavioral data we work . . . We have an insufficient body of commonly accepted and systematically organized theoretical propositions confirmed by rigorous experimental evidence . . . Considerable scholarly effort has been devoted to a consideration of practice knowledge. Some of it is of an extraordinarily high level of insight and competence. We do have a body of descriptive propositions concerning the principles of practice. It is true that some of this thinking relies too heavily on psychosanalytic theory or dynamic psychology at the expense of other aspects of psychology. Perhaps even more damaging to current formulations is the relative neglect of the social factors and how they modify the psychic elements. The major deficit is the lack of integration between these practice formulations and generalized propositions about the phenomena with which practice is concerned. (4)

. . . the knowledge of social work . . . presents some disturbing characteristics. There has been no systematic attempt to validate this knowledge. The borderline between social work hypothesis and fact is often tenuous. A seemingly truthful, self-evident hypothesis achieves the status of a fact by sheer repetition. (5)

Mr. Kadushin offers an explanation for this tendency:

One might note that such a problem regarding knowledge grounded in practice is to be expected. The practitioner faced with a client . . . cannot wait for definitive answers. He must use what he has, even if the best has doubtful validity. Nor can he afford constantly to remind himself of the tentativeness of his answers. The practitioner converts hypotheses into certainties because only in this way can he work with the necessary security and assurance. Shop-ticism about one's tools and conviction in one's practice are inseparable attitudes. (6)

(3) Lester S. King, M.D., "Is Medicine an Exact Science?", *Social Work Research Group Newsletter*, No.16, Feb. 1954.

(4) Neffman, Isaac L., "Research, Social Work and Scholarship", *Social Service Review*, Vol. 30, 1956, p. 24.

(5) Kadushin, Alfred, "The Knowledge Base of Social Work", *Issues in American Social Work*, by Alfred J. Kahn, p. 43.

(6) Ibid. p. 43.

This unquestioning reliance upon unvalidated "knowledge" seems less appropriate to the learning situation than it does to the practice setting, however. The error of mistaking hypotheses for fact in the educational setting may be understood by the fact that most of the persons teaching and writing on the subject of social work may have previously assimilated this attitude of confidence in the infallibility of their methods and knowledge while they were in practice. When social workers change from the role of practitioner to one of disseminating knowledge to others, the attitude of receptivity to change and openness to alternative formulations of theories and techniques seems more appropriate to the goal of improving the effectiveness of social work practice.

Greenwood is critical of the present status of social work education:

Unless and until the social work profession develops typologies of its problems and procedures, its concepts will remain indefinite, its language loose, and its textbooks vague. It is worth pondering to what degree the well known traumas of social work education are attributable to the psychiatric involvements that training entails and in what degree to the insecurities that unstructured subject matter and instruction must inevitably generate in social work students. (7)

I believe Greenwood is implying by "well known traumas" the reaction students have to psychoanalytic content. The literature abounds with suggestions for handling the students' resistance to the threat of psychoanalytic insights into

(7) Greenwood, Ernest, "Social Science and Social Work: A Theory of Their Relationship", Social Service Review, Vol. 22, 1955, p. 28.

themselves. Greenwood suggests rather that the students' reaction may be related to inadequate communication of clearly defined concepts and terms, and their inability to see a unified, logically inter-related body of knowledge and practice theory emerging.

Greenwood discusses practice theory in social work:

If we were to take what today passes for practice theory in social work . . . we would find that it has been built up in the main in a trial and error, crudely empirical and highly pragmatic manner. Social work practice theory has not developed via systematic research which converted social science laws into principles. It was constructed by social work practitioners who were untutored in the canons of scientific inquiry and who relied solely upon the richness of their insight and the wisdom derived from their day to day experiences on the job. (8)

In response to some of the above mentioned inadequacies the following suggestions were found in the literature:

Suggested Improvement Measures:

In view of aspiring toward recognition of social work as a profession, Hoffman had this to say:

Basic consideration should be given to the presence of a systematic body of knowledge of both practice procedures and phenomena descriptions, on which the performance of that profession rests. It must not only systematically formalize its practice theories, but it must also take on the task of developing a body of scholarly knowledge about those aspects of human behavior and social reality which are its own distinctive areas of specialization. As I see it, this differentiation can best be made around social work's primary concern with psychosocial dysfunction. (9)

The rational integration of the behavioral science and practice and with the social sciences (10) and practice has been

(8) Ibid. pp. 27-28.

(9) Hoffman, op. cit., p. 22.

(10) Some writers include psychology in the term "social sciences", although the term "behavioral sciences" is a more specific and less inclusive term referring to psychology.

scarcely considered. What impresses me is that there has been relatively little cross fertilization between clinical psychology and social work in its common areas of concern, except on an essentially procedural and operating structural basis. In terms of logical connection and interdisciplinary relationship, the areas of common concern, as well as of difference, are far greater for social work and clinical psychology than they are for any other professions with which social work has contact. There is as much need to relate the behavioral sciences to social work as there is to achieve that relationship with the social sciences. Or stated more exactly the problem is to relate the behavioral and social sciences with social work in an integrated fashion. (11)

Groveswood sees an analogy between social work and medicine in terms of their dependence on specialized sciences:

The great strides of medicine have been possible when medical research involved the medically untrained biophysical scientist, who brought to bear upon the medical problems the knowledge accumulated by the sciences . . . If any moral can be derived from this it is that efforts by social workers to refine their practice theory are destined to bear meager fruits if the social sciences are ignored. (12)

Problems to be overcome such as communication difficulties and abstract form characteristic of the social and behavioral sciences are stated by Groveswood:

The strong desirability still to necessity for social work to utilize the findings of social sciences in gaining wide acceptance. However, due to the fact that most social science disciplines have a technical language of their own and because the theoretical formulations are too abstract in form to be directly applicable to problems of practice, these must be converted into form suitable to practitioners. (13)

It is hoped that the writings on psychotherapy used by psychologists in their practice will satisfy most this requirement.

Summary of the Problem or Main Object:

(11) Hoffman, op. cit., p. 23.

(12) Groveswood, op. cit., p. 22.

(13) Ibid., p. 23

An absolute prerequisite to the use, by social work practitioners, of social science findings in the application of techniques visibly available to social work . . . The most effective method of insuring maximum utilization of social science (according to theory) by social work is to convert social science knowledge principles of practice. (14)

Receptivity of Social Work to the Social and Behavioral Sciences:

Jeanette Remondsen, in her report of the curriculum study, is representative of many writers:

We have found it apparent that social work and social sciences are a prerequisite for professional education, though our students are able to relate to the ways in which such knowledge can be adapted to knowledge for social work and their roles in social work practice. (15)

A receptive attitude is conveyed by Stein toward the behavioral sciences:

We are now in a position to assimilate, without great commotion, the research findings and the new knowledge that emerge from the behavioral sciences. (16)

Other Similar Studies:

To my knowledge only one other similar study has been done. A study conducted at the School of Social Work at the University of Wisconsin by Earl Neillon in 1954 revealed that there was a great deal of difference between personality courses in social work and psychology.

Identical questionnaires asking for literature used in personality courses were sent to 76 departments of psychology and 50 schools of social work. This section from the 44 usable

returns from psychology and the 25 returns from social work
(17)
is summarized as follows:

The books referred to in the returns were classified as type A if the author's "main theories stemmed from a psycho-analytic base", while authors of type B books "used other concepts of personality development instead of or in addition (18) to psychoanalytic concepts". Social work used type A books 73.1% and psychology's responses for type A books was 15.0%. (19) Most of social work's type B books were not really on personality, but were on medicine or were auto- (20) biographies or related to child care.

Vaillen's hypothesis that "personality courses in social work were slanted in one theoretical direction - psychoanalytic" - was duly supported.

This writer had originally planned a study similar to Vaillen's but decided it was unnecessary when Vaillen's study was discovered while reviewing the literature. It was wondered if the greater Freudian psychoanalytic emphasis in social work than in psychology would also exist in case-work courses.

The writer guessed that the difference between case-

(18) Ibid., p. 14.

(19) Ibid., p. 26.

(20) Ibid., p. 27.

work courses and psychotherapy courses would not be as great in terms of psychoanalytic influence as had been found to exist in the personality courses in social work and psychology. This study was designed to determine to what degree casework literature differed from that used in psychotherapy courses in psychology and the nature of the differences - not only differences in the personality theory orientation of the authors, but also differences in goals of therapy or casework and methods of achieving them.

Another stimulation for the study was the relative absence of books on the subject of psychotherapy in our casework bibliographies. I was surprised to find 30 books cataloged at the Michigan State University library on psychotherapy, 60 of which have been written in the last 10 years. I wondered if other schools of social work were also ignoring these books. It seemed highly probable that much of this literature would be found useful to social work, especially for training caseworkers. If the goals between social casework and those of these writers are similar, and if the methods are found to be within the possible range of casework function, variation in the technique suggested seems worth exploring and considering.

The purpose of this study is, therefore, twofold - (1) to determine differences inferred from the literature used between social casework and psychotherapy as practiced by clinical psychologists and (2) to compile a ranking according to popularity of books used by each discipline so that if social work instructors decide to broaden to include more

books on psychotherapy they will know which books are most used by others.

The project is directed toward answering the general question - Are we in social work neglecting or ignoring a variety of resources which may be useful in helping us attain our espoused ends? To the extent these ends are similar between books used in psychology and social work, the difference in means or methods should be considered for incorporation and integration into social work methodology, providing these means fall within the range of possibilities for our profession.

CHAPTER III

Design of the Study

The following hypotheses were used to guide the collection and analysis of the data. It proved impossible, because of the time factor, to devise and carry out reliable methods of collecting sufficient data to support or reject each of the following hypotheses. Hypothesis 1 was easily testable. Hypothesis 2 was tested by classifying the most popular books according to the authors' personality theory orientation. This is reported in Chapter IV. In considering differences in goals, techniques and eligibility requirements of the client, only an examination of the 10 most popular books was accomplished. An analysis of these variables will be given in Chapter V. The analysis of data related to hypotheses 3, 4 and 5 was also limited in scope. The writer will give his subjective impressions in Chapter V, based on the degree of reading the listed books which was accomplished. The data, in addition to supporting or rejecting the hypotheses, should have implications for the inclusion or exclusion of the new material studied into training courses of social casework.

The hypotheses are as follows:

Hypothesis 1. There will be a greater number of texts, principle books and recommended books referred to by psychology instructors than social work instructors.

Hypothesis 2. There will be more variation between the books used in psychology than those used in casework.

Variation would be determined by an analysis of the book in question according to differences in:

I. Author's theoretical orientation - types of personality theory advocated.

II. Therapeutic techniques advocated or differences in emphasis on:

- 1) Directiveness versus non-directiveness (or active versus passive)
- 2) Importance of the unconscious
- 3) Use of unconscious material in treatment
- 4) Importance of early experiences
- 5) Use of recalled early experiences in treatment
- 6) Use of transference
- 7) Interpretation of motives of behavior
- 8) Uncovering methods
- 9) Use of free association
- 10) Use of ventilation
- 11) Use of reassurance
- 12) Ego supporting
- 13) Environmental manipulation
- 14) Therapist demonstrates respect and acceptance
- 15) Giving advice
- 16) Educating
- 17) Use of learning theory
- 18) Importance placed on interpersonal relationships
- 19) Importance of intellectual understanding
- 20) Importance of emotional experience

III. Variation in goals (explicit or implicit) - Is the method designed to be effective for:

- 1) Personality structural changes
- 2) Changes in types of defenses or patterns of adaptations to environment
- 3) Changes in degree of strength of core defenses in relation to others
- 4) Improving adequacy of functioning
- 5) Improving interpersonal relationships
- 6) Increasing the clients' general subjective state of pleasure and happiness

IV. Variation in qualifications or characteristics of the client required to be a candidate for treatment:

Is the treatment method designed to be effective for any client? Here, I would estimate the varying effec-

tiveness of this treatment with various types of mental disorders as outlined by the Diagnostic and Statistical Manual, American Psychiatric Association, 1952.

Hypothesis 3. The overall differences between the analysis of books in social work and psychology will be no greater than the variation between books used in psychology. (That is to say, the range of differences in psychology is as great or greater than the differences between social work's books and psychology's books.)

Definition - the overall differences will be the differences in distribution of books according to the factors outlined under Hypothesis 2.

Hypothesis 4. The similarities between books in social work and books in psychology according to the above outline are greater than between social work and orthodox psychoanalysis.

Methods of psychoanalysis were to be analyzed according to the above outline.

In testing all of the above hypotheses, comparison of specific characteristics of the 4 divided areas of analysis may be done. For example, a variation may exist in methods but not in goals - or a variation may exist in personality theoretical orientation but not in methods.

Hypothesis 5. There is more similarity between case-workers' goals and the psychotherapists' goals than there is difference.

Testing this hypothesis will be accomplished by comparisons under III above.

The reader may have difficulty perceiving what, if any, significance these hypotheses have. That is, of what value it is to know this information. Implicit in the writer's thinking in desiring to test these hypotheses is the belief that psychological practice courses are, for the most part, attempting to prepare clinicians to achieve the same ends social caseworkers are, and that psychology draws from more diversified literature, most of which is as germane to social work as it is to psychology.

Limitations in the Design:

The scope of this project is so broad that it was impossible to do an accurate and carefully controlled analysis. If all of the characteristics listed under hypotheses 2 were ferretted out and carefully compared in each book analyzed, and a relative value assigned by a number of independent judges, and agreement between judges was high, the hypotheses could be supported or rejected with some degree of certainty. The present design fails to control for the biases of the observer. However, the list of books being compared should be reliable and valid. Where doubt exists concerning the classification of them and the assigning of relative values to their characteristics, the raw material (the books) is readily available for inspection and observation by others and the conclusions of this study can be checked against the subjective evaluation of others.

Method of Securing Data:

Questionnaires, very similar to those Maillen used, were sent, asking among other things for "texts", "princi-

ple books" and "especially recommended readings". A copy of the questionnaire is shown in Appendix I. Enclosed with the questionnaire was a cover letter by the Director of the School of Social Work at Michigan State University, a copy of which appears in Appendix II.

The other data was observations of the books themselves and classification of their characteristics as suggested under hypothesis 2. Because of conditions of time and availability of books, information from abstracts, book reviews, and/or opinions of others who were familiar with the books were also used.

The questionnaires were sent to all accredited schools of social work in the United States and nearly all schools offering courses in either psychotherapy or psychological counseling in departments of psychology.

The mailing list can, therefore, be considered a canvas of the universe to be studied and the returns be considered a sample from that universe.

CHAPTER IV

Analysis of the Data

Results:

Fifty-six accredited schools of social work were sent questionnaires and 29 (52%) were returned. Two others were returned unusable because they were not filled out. The recipient did not understand what was wanted. Twenty of the returns contained bibliographies. There were about 500 pages of bibliographies in all. They ranged from 2 to 100 pages in length, averaging 25 pages. The mailing list was taken from the July 1960 list of Graduate Professional Schools of Social Work published by the Council on Social Work Education. The entire list was used with the exception of the Canadian schools.

Fifty-two departments of psychology were sent the same questionnaire. Twenty-eight (54%) were returned in time to be processed. One was returned too late to be included. Twelve of these returns contained bibliographies. These bibliographies were much shorter, containing fewer articles. There were 76 pages in all. They ranged from 3 to 27 pages having a mean of 6 pages. The mailing list for the departments of psychology was assembled by the use of a list of approved schools offering a Doctorate in clinical or counseling psychology appearing in The American Psychologist.
⁽²¹⁾

(21) American Psychological Association Education and Training Board, "Doctoral Training Programs in Clinical Psychology and In Counseling Psychology", The American Psychologist, Vol. 15, June 1960, p. 361.

To be sure that a course in psychotherapy or counseling was offered by these schools, the catalogs of the respondent schools were inspected. This also provided a means of addressing the questionnaires to the instructors concerned, whenever this information was included in the catalogs. Some of the catalogs were not available in the Michigan State University library and others reflected that no formal course on psychotherapy was offered. Four catalogs were not available but questionnaires were sent anyway. Five schools offered no course according to their catalogs and so were not included. Catalogs of schools not on the list in The American Psychologist revealed five other schools which offered courses on psychotherapy and were mailed the questionnaire.

Organization of the Data:

The questionnaire asked for 1) "text", 2) principle books from which you require your students to read" and 3) "books you especially recommend". Most of the returns did not clearly differentiate between the last two categories and this researcher finally decided to use the following operational definition to make these distinctions. Books included in bibliographies but undesignated were classified as "especially recommended". Therefore, this term is misleading and the term "mentioned books" will be substituted for it in this paper. Books were assigned the classification of "required" if they were so designated by the instructor or if outlines of courses revealed that assignments were made from particular books in the bibliography. Several schools sent short lists of books which were not differentia-

ted between required and recommended. If the list did not exceed 15 books, they were considered required. It was unfortunate to have to make these arbitrary decisions, but the possible error introduced should apply equally to schools of social work and departments of psychology and should not bias the results in either direction.

Information from the returned questionnaires and bibliographies was transcribed onto 3x5 cards and it was found that social work questionnaires and bibliographies referred to a total of 401 books and psychology referred to a total of 220 books. There was a card for each book upon which was recorded the number of times that that book was used as a text, was required or was just mentioned on the bibliography.

In order to get a single unit of measurement which reflected the general degree of use of a book, it was decided to multiply the number of text responses by 3, add the number of required responses multiplied by 2, and add the number of mentioned responses to obtain what will be referred to as a
(22) weighted score.

In terms of weighted score, social work had a total of 1230 distributed over 401 books. The mean was about 3 points weighted score. Psychology had a total of 1061 distributed over 220 books. The mean was 4.3 weighted score.

-
- (22) After tabulating the data I concluded that this weighted score system gave too much weight to books which were only mentioned on bibliographies. It would seem that a book used as a text receives more use than one simply mentioned on three bibliographies. This would not seem to alter the conclusions reached in this paper, however.

The writer then ranked these cards from highest to lowest in terms of weighted score and noticed that the 34 highest ranking books from psychology earned 530 weighted points which is half of the 1061 total. Correspondingly, the highest 42 books from social work contributed a total of 126 weighted points, which is just 7 points more than half of the 1230 weighted points attributed to all books mentioned by social work. This dividing line was used because it included all books with a weighted score down to 5 in social work and down to 8 in psychology, rather than use only part of the books receiving the same score. This group of books from each discipline can be considered to be used "the majority of the time", due to their receiving one-half or more of the total weighted points. They are listed in rank order on Table I for psychology and Table Ia for social work. It was decided that this group of books would be sufficiently representative to draw conclusions from concerning similarities and differences between these two disciplines.

When Tables I and Ia are compared it is found that only the two most often used books in psychology are among the 42 books that social work used "the majority of the time". Social work's combined weighting for these two books is 16 points. This overlap constitutes 1.29% of social work's 1230 points. These books earned 69 points by psychology instructors which is 6.4% of the total 1061 total points in psychology.

It can be observed from Tables I and Ia that the books earning half the total weighted points in social work range from 6 to 66, whereas the range in psychology is from 9 to

35. Seventeen of social work's books were used less frequently than any on Table I by psychologists. On the other hand, the first two books on Table Ia earned almost twice the number of points as did the highest books by psychology. It therefore is apparent that the distribution of points in social work is more skewed, being higher on one end and having a longer tail.

Comparing the books on Tables I and Ia there seem to be more books in social work that are related to giving information of a psychological nature or aimed at understanding various types of problems in contradistinction to an orientation toward practice per se. Fourteen books were so classified by the writer (numbers 4,9,10,11,12,14,16,18,23,24, 27,29 and 41). The total weighted score for these books is 134 points. This is 30% of the total points for Table Ia. The fourteen books represent 33% of the total 42. In Table I there seem to be only 3 books which were oriented toward theory rather than practice. Numbers 9, 11 and 22 earned 43 points which is 8% of the total points for Table I and 9% of the total books. Whether or not the difference between the proportion of informational type books could have resulted due to chance factors in sampling was investigated. The standard error of the difference between two proportions is .0056 producing a standard score of 2.51. When this is compared to the normal distribution it is evident that a difference between the proportion .09 and .33 could have occurred by chance only 1.4% of the time when both ends of the curve are considered. Therefore, we can reject the null hypothesis

that the two disciplines use the same proportion of information type books at the .025 level of confidence.

The study of Maillen (referred to in Chapter II) had shown that courses in personality were more psychoanalytic in social work than in psychology. This writer felt that this difference would not be found in casework courses also. It was hypothesized that the overall difference between books in social work and psychology would be no greater than the differences within each discipline. A measure of this difference was to be based on:

1. The author's theoretical orientation - type of personality theory advocated,
2. the general therapeutic technique advocated,
3. the therapeutic goals sought and
4. the degree of selectivity of involved in being an eligible client.

Time did not permit analysis of differences in a sufficiently systematic manner for discriminating on the basis of items 2, 3 and 4 above. Some impressions were gleaned related to techniques, goals and selectivity of eligible clients and will be discussed at the conclusion of this thesis. The writer did classify the books on Tables I and Ia on the basis of the authors' apparent personality theoretical orientation. Instead of making two classes as Maillen did (psychoanalytic and non-psychanalytic), the writer used three categories - Freudian, neo-Freudian and non-Freudian. Authors who revealed no significant departure to orthodox Freudian personality theory were classified Freudian. For

example, if their writing reflected no departure from instinct theory and psychosexual developmental stages in which biological rather than environmental factors are emphasized, the authors were considered Freudian. They were also classified as Freudian if their attention centered predominantly on unconscious determinants of behavior which was largely attributable to drives or instincts and defenses against them rather than perceiving behavior as predominantly governed by factors of past learning plus the immediate stimulus situation, which typifies those authors classified as neo-Freudian. The neo-Freudian group, in addition to the above, is differentiated by their greater emphasis on consciously perceived reality factors in the stimulus situation and they generally integrate knowledge and theory derived by Behavioristic (learning theory) psychology, sociology and anthropology. However, Freudian concepts and terminology, to a greater or lesser degree, comprise a large part of their frame of reference. The term eclectic was also attached so as to include writers which present a variety of approaches usually involving orthodox psychoanalysis - for example, Harper and McCary and Chodor.

The third category includes all those which don't fit the above two classes. Some, like Rank, were originally associated with Freud, but the similarities are less great than the differences in terms of personality theory.

This writer attempted to base his decisions on the author's personality theoretical orientation rather than the similarities or differences in the manner he advocated practicing psychotherapy or casework. It appears that the cor-

relation between theory and practice is not particularly high, especially in casework.

For example, authors like Hamilton who draw no derivation from classical Freudian theory, always little use of interpretation of unconscious material or transference phenomena. And Franklin another example of a changing strategy with clients to be ego supporting, etc.

On the other hand, many of the authors classified as non-Freudian may use psychoanalytic methods of free-association, etc.

No comments concerning the apparent differences between these categories will be given in the discussion section of this paper.

Tables II and IIa show the classification discussed above. The weighted score was used as a measure of the extent that these books were used. Table III compares the percentage of use for each discipline as well as the number of books in each category. A test for statistical significance between the proportions of responses (in terms of weighted score) attributed to non-Freudian authors by psychology and by social work was made. The standard error of the difference between two proportions was .0161 and the standard score was 8.00, which is significant. With less than a .001 probability of making a type I error, it can be said that psychology uses non-Freudian books more than does social work. Conversely, with greater confidence, it can be stated that the difference between psychology's and social work's use of Freudian authors is statistically significant. The standard

TABLE III
Summarized Information From Tables II and IIa

	Social Work		Psychology	
	Responses	Books	Responses	Books
Freudian	44%	20	31%	9
Neo-Freudian or Eclectic	45%	17	44%	14
Non-Freudian	11%	5	25%	9

error here was .0145 and the standard score was 2.0.

It was wondered if the difference between psychology's use of Freudian (31%) and neo-Freudian (44) was statistically significant. A standard error of the difference between two proportions of .0195 was found and a standard score of 3.1. This is also significant at the .01 level of confidence.

Tables IV and IVa show the books by psychology and social work respectively which earned a total weighted score of 3 or more but less than enough for Table I or Ia. This might be described as the middle area if one thinks of the frequency distribution over the range of points.

Table IV contains 25 more books than does Table IVa, despite the fact that social work mentioned nearly twice as many total books as did psychology. All of the books in psychology earning 3 points or more make up over half of the total number of books mentioned by psychology, whereas the books in social work that are that popular constitute less than one-

quarter of the total. The remaining three-quarters were 300 in number. Of these, 210 were mentioned by only one school and 94 were either mentioned by two schools or required by one. In psychology 62 books were only mentioned by one school and 42 by two schools. Therefore, when considering books that are used by at least two schools, there are slightly more used by psychology than by social work - 116 and 99 respectively. In other words, there is more agreement between schools of psychology in the books they use than in social work, with the exception of the three most popular books in social work. This is apparent when the total responses in Tables IV and IVa are compared. There are 3 text responses and 100 required responses by psychology and 1 text and 54 required responses by social work. There were also more required responses by psychology in Table I, although social work had more text responses on Ia.

Tables V and Va show the overlap - books mentioned by at least one school in each discipline. Both the Tables contain the same books, but Table V is ranked for psychology and Table Va for social work. A coefficient of correlation of .07 was found between the two weighted scores of each discipline. Therefore, it can be said that there is no relationship between the degree that these books are used by psychology and by social work. These books in this overlap category are much less popular in social work than in psychology. In psychology there were 6 text responses and 94 required, and in social work there was no text response and only 30 required responses. The mean for psychology's responses was 6.1 and

social work's was 3.4. Both of these means are slightly greater than the means of their respective total points, however.

The 175 weighted points for social work is 14% of the total 1250 points, which is a measure of relative use of the books in the overlap. The Table contains 52 books which is 13% of the 401 books used in social work. Correspondingly, psychology used these books 30% of the total according to the weighted score, and Table V contains 24% of their total books. The combined weighted scores of psychology and social work for all overlap is 21% of the combined total weighted scores.

The questionnaire asked for course outlines if they

were available. Eight outlines were received from schools of social work and 6 from psychology. The social work outlines were more lengthy, 59 pages in all, with a mean number of 7.4 pages and a standard deviation of 9.52. Six outlines from psychology departments contained 17 pages, a mean of 4.2 and a standard deviation of 2.3. Applying a student's "t" it is found that the difference between these means is not statistically significant.

M.= Mentioned

T₁.= Total (Weighted Score)

In order to reflect similarities or differences between the two disciplines, a composite outline for each of the disciplines was attempted. This is shown on Tables VI and VIa. The number on the righthand margin reflects the number of outlines containing the item. Paraphrasing was done to consolidate basically similar items.

It can be seen from Tables VI and VIa that the overlap of similar items varies from 13% of the social work items to 30% of the items in psychology. There are more items that appeared on only one outline from social work (35%) than there were in psychology (17%). Although there were more outlines from social work, the mean frequency that an item appeared on an outline was nearly identical, 2.6 and 2.7 for

social work and psychology respectively.

The unshared items reflect the differences between the two disciplines. Viewing Table VI it can be seen that courses in psychotherapy offer a variety of theoretical approaches, the majority of outlines listing at least five approaches. Group psychotherapy and psychotherapy with children were covered by half or more of the outlines. Psychology is distinguished from social work in instructing on free association, hypnosis, resistance, dream interpretation, psychological tests and termination, according to the outlines.

On the other hand, 37% of the items appearing in social work outlines are apparently not taught in psychology. Because the social work outlines tended to be longer, it is likely that some of the items may be taught under the broader headings used by psychology. Due to the difference of terminology many items may be implicit in other categories. However, there remain many items which do not seem relevant to psychotherapy and represent unique social work functions.

Based on the literature used by psychology the following headings seem to be unique to or emphasized by social work: Agency functioning, Recording, Eligibility and Intake, Financial assistance and Budgeting, Referral, Child welfare, Medical care, Use of community resources, Home visits, Problems of aging, Supervision, Recreation, and Modifying the environment.

From Tables VI and VIa it could be concluded that case-work courses cover a greater range of subject matter than do psychology courses. Most of what is taught in psychology

courses seems to be logically fit within the context of the goals and purposes of social casework. If one focused on that aspect of social casework sometimes referred to as casework therapy, or the task of offering help through verbal interaction aimed at restoring the clients' social functioning, it would seem that most of the material covered by psychological outlines is highly relevant to enhancing the caseworkers' skills. There seem to be only two items in the psychological outlines which are not germane to social work, Psychological testing and Hypnosis. Other items seem conspicuously absent from social work outlines, such as Group psychotherapy, Psychotherapy with children and with psychotics. Resistance seems equally important to social work as does Termination.

The questionnaire asked for the length of the courses in quarters or semesters. When the quarters were converted into semester equivalents by multiplying by 2/3, the range, means and standard deviations could be computed. Social work had a mean of 3.24 semesters and a standard deviation of 1.07 with a range from 1 to 4. Psychology courses ranged from 2/3 of a semester (1 quarter) to 4 semesters, but had a mean of 1.57 and a standard deviation of .5. The student's "t" test was applied. The standard error of the difference between the two means was .615, producing a "t" score of 2.39 which is significant at the .0105 level of confidence. Therefore, it is concluded that a difference this great is not due to sampling variability, but represents a real difference.

Another roll of incidental question that was asked in the questionnaire was whether or not a text was used. The psychology returns indicated 14 schools did and 14 did not use a text. The social work returns were not much different - 17 did and 13 did not use a text. It was wondered if this difference was statistically significant. The standard error of the difference between two proportions is .130. The difference between these two proportions was .00. The obtained standard error of .10, when compared to the normal distribution, reveals that a difference this small could have occurred by chance 50% of the time and it would be unsafe to believe this difference is real. It is too likely to be the result of sampling variability.

CHAPTER V

Content Analysis of the Books Reported by Social Work and Psychology

Chapter IV reported the data which was collected through the questionnaires and analyses concerning all relationships found to exist in the data. This chapter will relate the data more directly to the hypotheses in Chapter III, from the data in Chapter IV as well as some of the content of the books listed in Chapter IV.

Hypothesis 1 was discussed in Chapter IV.

Hypothesis 2 stated that there will be more variation between the books used in psychology than in casework. It was predicted that psychology would 1) present a greater variety of personality theoretical orientation, 2) vary more than social work books in terms of their emphasis on 20 methods or techniques emphasized (listed on page 14), 3) vary in terms of goals striven for and 4) vary in prerequisites for being an eligible candidate for treatment. Hypothesis 3 states that this variation within psychology will be as great as the difference between psychology and casework.

Concerning hypothesis 2 it was found that authors used in psychology were more equally divided into three personality orientations - Freudian, neo-Freudian (or eclectic) and non-Freudian (31%, 44% and 25%) - than were social work authors (44%, 45% and 11%). That is, whereas 29% of social work authors were either Freudian or neo-Freudian (or eclectic), only 75% of psychology authors

fall into this group. While this difference is not striking, examining the returns individually showed that most departments of psychology (over 2/3) gave considerable attention to both opposing type authors, Freudian and non-Freudian. This is evident from the fact that one of Roger's books, *Introspection*, earned only 3 points less than the most popular book, and the highest Freudian author is next. Only two or three departments of psychology could be said to be slanted in either the Freudian or non-Freudian direction by an absence of required books from both orientations. The few returns not demonstrating a balance of approaches referred to a much smaller number of books and did not send bibliographies.

Also tending to support hypothesis 2 is the fact that 4 of the "most used books" in psychology are designed to acquaint the reader with a variety of alternative approaches to library. These are Wilberg, Monroe, McCay and Cramer, and Harper. Harper, by the way, describes 76 differing systems of psychotherapy. These books earned a total weighted score of 73 which is 14% of the total weighted score for the "most used books". These books have a mean of 18.2 which is greater than the mean score for the "most used books" on Table I of 15.6. This means these books are used more than the average of the "most used books".

In addition to the Wilberg, Monroe, a variety of approaches. His weighted score in social work of 9 is only 1% of the total weighted score for the "most used books", and he was used less frequently than the 14.6% average of "most used books".

The findings, however, do not support Hypothesis 1, which predicted a more equal balance between these theoretical orientations in psychology; however, utilization of books offering diversified approaches and the fact that over 2/3 of the returns and outlines offered a balanced menu of even antithetical approaches.

Hypothesis 2 also predicted that psychology's books would show more variation in emphasizing 20 specific therapeutic techniques than would social work.

The 10 most popular books in psychology were examined for each of these 20 variables and a value from 0 to 10 assigned. The larger the number the greater the emphasis was felt to be given that particular factor.

Table VII shows the values assigned to each author for the 20 aspects of therapy. Reading down the columns gives a picture of how that author emphasizes various aspects of therapy and reading across shows the range of differences that exist between different authors for a specific technique or aspect of therapy.

The authors are separated into 3 groups - Freudian, non-Freudian and non-Freudian and appear to vary less within these groupings than between them, although not consistently so.

The horizontal values were added and the means found. Then the absolute (either positive or negative) variation from the means were totaled and divided by the number of authors. This is called the mean deviation (M.D.) and is shown for each variable on Table VII. The average of all these mean deviations was 1.0.

Time did not permit the same procedure for the 10 most

M = Mean

M.D. = Mean Deviation (the sum of the absolute deviations from the mean divided by the number of books)

Average Mean 5.05
Average M.D. 1.90

popular books in social work. It is expected that persons reading this paper will be more familiar with the social work literature than with that used by psychology anyway.

Based upon this writer's familiarity with social work literature it seems safe to say that our authors show much more agreement and less variation concerning these 20 aspects of therapy.

Using the same frame of reference as for assigning these values for psychology's authors, Table VIII shows the values this writer assigned to social work literature. These values should be comparable to the mean values of the 10 psychology authors, although they were not derived by the analysis of each book separately.

The mean deviation between social work's mean and psychology's mean is 2.56.

Hypothesis 3 states that the overall difference between psychology's and social work's books will be no greater than the differences within psychology. Evidence for the support or rejection of this hypothesis was in part variations in therapeutic technique examined on Tables VII and VIII. If the internal variation between authors in psychology (represented by the average mean deviation of 1.0) is sufficiently smaller than the average difference between social work's and psychology's values, 2.56, hypothesis 3 can be rejected insofar as therapeutic techniques are concerned. However, because of the subjective nature under which these values were assigned, testing for statistical significance would tend to lend more credence to this difference than is justifiable. However,

TABLE VIII

Mean Values of Social Work Authors for Various Aspects and Techniques of Casework as Compared to Psychology

	Extent Encapsulated By Social Work / Psychology (Mean)	Difference
1. Directiveness	4.7	+ .3
2. Use of unconscious	5.7	+ 1.0
3. Use of unconscious in treatment	5.7	- .1

16. Educating	5.5	+ .6
17. Use of learning theory	5.1	- .4
18. Interpersonal relationships	5.8	+ 1.2
19. Intellectual understanding	4.9	- 1.0
20. Therapy (emotional experience)	6.1	+ 1.0

$$M.D. = \frac{\sum |x|}{N} = 2.56$$

this difference of .66 does not appear to be significant.

Therefore, hypothesis 3 cannot be rejected by the examination of therapeutic differences between psychology and social work.

Inspecting the differences that do appear on Table VIII might be useful, however, for describing differences between psychology and social work. The last column of numbers shows the difference between the hypothetical mean of social work and psychology's mean of the 10 books. Plus (+) numbers indicate social work emphasizes that technique more than does

psychology, and minus (-) numbers indicate the reverse is true.

Keeping in mind these are the writer's evaluations based on impressions from reading the books, the following statements are offered.

Social work seems to emphasize directiveness - therapist activity in eliciting client responses; ego supporting techniques; environmental manipulation; love, respect and acceptance; advising; and educating - more than do authors used in psychology. On the other hand, psychology emphasizes to a greater degree than does social work such items as - use of the unconscious; use of transference; interpretation in general; uncovering techniques; free association; use of learning theory and intellectual understanding.

Hypothesis 2, concerned with more variation in psychology than social work, and hypothesis 3, concerned with the variation within psychology being no greater than the variation between the two disciplines, were also tested by analysis of the literature relating to their goals of therapy or casework, as well as variation in qualifications or characteristics requested for the client to be an eligible candidate for treatment.

Here again, the writer had to make compromises with the original design because of the time consumed in processing the returns, and can only compare my impressions from the 10 most popular psychology books with my impressions of the general social work literature.

Psychology shows more variation between authors in terms of their goals than does social work, but in general gives

greater emphasis to:

1. personality structural change
2. changes in types of defenses or patterns of adaptations to the environment.

Social work and psychology authors seem equally to endorse:

3. changes in the degree of strength of some defenses in relation to others,
4. improving adequacy of functioning (though here social work may have an edge),
5. improving interpersonal relationships (here some psychology authors, Sullivan, Fromm-Reichmann, etc., outdistance social work authors, but are balanced by those less interested in interpersonal relationships, such as Cloby, Menninger and Alexander and French), and
6. increasing the clients' general subjective state of pleasure and happiness.

The fact that social work appears no different from psychology in respect to 4 out of 6 goals examined lends added support for hypothesis 3 concerning the similarity between the two disciplines.

Hypothesis 5 states specifically there is more similarity between the caseworkers' goals and the psychotherapists' goals than there is difference. This hypothesis was not sufficiently or systematically tested, but the above judgment that social work's and psychology's goals are more alike than different is based on the examination of the 10 most used psychology books and several lesser used books, and general reading of social work literature. This judgment was influenced by sev-

eral recurring types of statements in the literature used by psychology:

1. most prefaces of books used by psychology specifically state that the book is expected to be useful to psychiatric caseworkers as well as psychiatrists and psychologists,
2. in defining psychotherapy the writers usually give mention to social casework and their definition includes it, though sometimes under the differentiation of supportive or re-educative psychotherapy,
3. the goals specifically referred to by these authors are, for the most part, indistinguishable from the goals of social work.

This is understandable when one observes that the highest 10 books in psychology, with the exception of Freud's Collected Papers, represent significant departures from orthodox psychoanalysis. These departures seem to have these things in common:

1. shorter duration or frequency of therapist-client contact,
2. focus on problems which currently disturb the client's functioning or cause discomfort,
3. the therapist more actively participates in the therapeutic process (except for Rogers),
4. their methods are designed to treat a greater range of problems, at less cost, thereby reaching the majority of clients who, for one reason or another, are ineligible for orthodox psychoanalysis,
5. they tend to focus on existing strengths rather than probing for weaknesses, and

6. they utilize current behavior, rather than the past, for interpretation, either exemplified in the client-therapist relationship or in daily living, more than does orthodox psychoanalysis.

It seems obvious that these characteristics are equally descriptive of social work. (In much of the reading this writer received the impression that the author was describing social casework, though using different terms, which, by the way, seemed more articulate than is the social work vernacular).

In the original design it was planned to test hypothesis 4 - that the similarities between books in social work and books in psychology are greater than between social work and orthodox psychoanalysis - by the same method as was used for the other hypotheses. The above comments are related to this hypothesis in the direction of supporting it.

For additional evidence for hypothesis 4, the writer found the difference between the social work (hypothetical) mean values on Table VIII and the values assigned to Freud's Selected Papers, shown on Table VII. If the difference between social work and Freud is greater than between social work and the mean for psychology for these 20 aspects of therapy, the hypothesis will be supported.

Table IX shows this comparison. The average difference, represented by a mean deviation (M.D.) between social work and Freud is 4.6. The average difference (M.D.) between social work's mean and Freud's mean was 0.56. This means that social casework's books are almost twice as similar to those used by psychology as they are to orthodox psychoanalysis.

TABLE IX

Comparison of Social Work with Freud on 20 Aspects of Therapy

	Social Work	Freud	Difference
1. Differentiation	6	1	+ 7
2. Use of interpretation	10	-	-
3. Use of imagination in treatment	10	-	-
4. Daily experiences (importance)	10	-	-
5. Early experiences (use of)	10	-	-
6. Use of transference	10	-	-
7. Interpretation	10	-	-
8. Uncovering techniques	10	-	-
9. Free association	10	-	-
10. Ventilation	10	-	-
11. Use of reassurance	10	-	-
12. Freeagrant	10	-	-
13. Therapeutic manipulation	10	-	-
14. Love, respect and acceptance	10	-	-
15. Advising	10	-	-
16. Educating	10	-	-
17. Use of learning theory	10	-	-
18. Individual relationships	10	-	-
19. Intellectual interpretations	3	-	-
20. Therapy (optional experience)	3	-	-

$$M.D. = \frac{\sum |x_i - \bar{x}|}{N} = 4.6 \quad \bar{x} = \text{absolute variation}$$

Because the numbers are based on values from 0 to 10, they can also be represented as percentages. Therefore, a mean difference of 4.6 can be represented as a 46% difference.

In terms of variation in prerequisites for client eligibility, psychology authors show considerable variation. Table X shows values from 1 to 10 indicating inclusiveness of various kinds of disorders that their method is expected to succeed with. The higher the number the more inclusive. It can be seen that there is considerable variation between authors and that the Neo-Freudian authors are more inclusive than either Freudian

TABLE X
Inclusiveness of Various Kinds of Disorders Treatable
By Methods Advocated by Psychology Authors (range 1-10)

		Deviation from M. Mean
Colby	4	- .0
Hanninger	4	- .0
Alexander & French	3	- 1.0
Freud, S.	1	- 3.0
Freud-Reichmann	3	+ 2.0
Nelberg	3	+ 2.0
Sullivan	3	+ 2.0
Bandler & Miller	4	- .0
Rogers	3	- 1.0
Alien	5	+ .2
	—	—
Mean	4.8	19.0

or non-Freudian authors.

The impression of this writer is that official world writers in general are about as inclusive, in terms of problems treatable, as any of the authors psychology uses, at least for supportive treatment objectives.

CHAPTER VI

Summary and Conclusions

Names of books used were obtained from 29 social work instructors of casework courses and 28 psychology instructors of psychotherapy or counseling courses. Social work reported 401 books but 210 of these were only "mentioned" by one school and another 94 by two schools. Psychology referred to 220 books altogether. Sixty-two of these books were "mentioned" by only one school and 42 by two schools.

Hypothesis 1 in Chapter III had stated that it was expected that psychology would use a greater number of books than social work. This is rejected if the total number of books used is considered. However, if only books that are "mentioned" by more than two schools are considered, psychology uses 25 more books than does social work. Therefore, the question as to which discipline uses more books is not clearly answered by this study. If one considers the number of books earning a weighted score of 9 or more, psychology has 34 and social work has 25.

Examining the "most used books" (Tables I and Ia) it was wondered if a difference existed between the two disciplines in frequency of use of books designed to give information rather than instruct for practice. Stated another way, some books seemed to be oriented toward understanding while others were oriented toward doing. Thirty-three percent of social work's books were of the information type and 21 of the psychology books were of this type. This difference is sta-

tistically significant.

The "most used books" were classified into 3 categories according to personality theoretical orientation of the author - Freudian, neo-Freudian and non-Freudian. Psychology used less Freudian and more non-Freudian authors than did social work but used neo-Freudian authors to about the same degree as did social work. This difference in theoretical orientation of the authors used in practice courses is much less great than the differences found to exist in personality courses between the two disciplines by Maillen in 1954.

It was wondered to what extent the two disciplines used the same books. The combined weighted scores of psychology and social work for the overlap is 21% of the combined total weighted scores of the two disciplines. This is very similar to the overlap found in Maillen's study,
(23) which was 14%.

A coefficient of correlation of .07 was found to exist between the measure of use of those books by the two disciplines, indicating that there is no relationship between the disciplines' relative use of these books.

Course outlines for the two disciplines were compared. The overlap of items reported by psychology's and social work's outlines were studied. The overlap constituted 13% of social work's items and 30% of psychology's.

Psychology differed from social work in terms of offering a variety of theoretical orientations, as was found

(23) Maillen, op. cit., p. 27.

in Maillen's study; and gave more attention to group psychotherapy, psychotherapy with children and psychotics.

Social work outlines covered many subjects not covered by psychology such as agency functioning, recording, financial assistance and budgeting, referral, child welfare, medical care, use of community resources, home visits, aging, supervision, recreation and modifying the environment.

Social casework courses were significantly larger than were psychotherapy courses.

Chapter V attempted to relate the content or characteristics of the books referred to by each discipline to the hypotheses in Chapter III.

The 10 most popular books in psychology were examined and evaluated in terms of their emphasis on 20 aspects of therapy. The values assigned to these 20 variables were compared to where the social work authors were felt to stand on these variables. Using these admittedly subjective methods, a difference of 26% was found to exist between these disciplines, which was a little greater than the variation within psychology which is reflected by a measure of 19%. This difference (7%) does not appear to be great enough to reject the hypothesis that there is more difference within psychology than between psychology and social work.

However, when social work is compared to orthodox psychoanalysis reflected by Freud's Collected Papers, a difference of 20% was found, lending support to the hypothesis that social work had more in common with current psychotherapy taught in the discipline of psychology than it does with orthodox

psychoanalysis.

The writer concluded from the literature used by psychology that their goals were more similar to that of social work than they were different.

Social work was felt to be a little more inclusive than was psychology in terms of a greater range of problems that casework methods were geared to handle. Within psychology the neo-Freudians were more inclusive than either Freudian or non-Freudian authors.

Conclusions and Implications:

After making the transition from psychology as an undergraduate student to social work graduate school, I was baffled by the discrepancy between the conception of psychology held by social work colleagues, instructors and writers and my own. They tended to more or less equate psychology with Freud and felt psychoanalysis enjoyed a high status in current clinical psychology. My undergraduate exposure was predominantly experimental and behavioristically inclined, wherein Freud was practically ignored. Realizing my exposure to psychology was limited I was sufficiently uncertain of my position to be interested in determining which conception of psychology was the more accurate.

Since doing this study I have concluded that both positions were inaccurate and clinical psychology, insofar as doing psychotherapy is concerned, lies somewhere in the middle in terms of Freudian, non-Freudian continuum.

Psychology instructors of psychotherapy use as many medical authors or more than do social work instructors. These

psychoanalytic authors are predominantly neo-Freudian, however. The few psychology authors like Rogers, Dollard, Harner and Mowrer, are used heavily but none is the most popular.

Perhaps the heavy borrowing from medical authors can be explained by the fact that clinical psychology has more recently attempted to assume some responsibility for doing and teaching psychotherapy than has social work.

The fact that psychology's interest in psychotherapy is more recent than is social work's may also account for some of the differences between the two professions. Social work, having assimilated psychoanalysis in the thirties before it had begun being modified by the neo-Freudian psychoanalysts, would naturally be more orthodox than a discipline becoming interested in the late forties and early fifties after much of the modification had already begun.

Yaillen's study found a tremendous difference between social work and psychology in terms of Freudian emphasis on the personality theory level. However, this study indicates that a similar difference does not exist on the level of practice, although social work is still more influenced by the Freudian frame of reference.

Interestingly, on the level of practice, social work is less Freudian than on the level of personality theory, but psychology is more Freudian oriented in practice courses than it is in personality courses.

This seems explainable when two factors are considered - one related to psychology and the other to social work. In psychology, personality courses may be offered to students

interested in understanding behavior for a number of reasons other than treating pathology. Freudian theory slightly has less utility in understanding normal or conscious behavior than do many competing personality theories. In courses on psychotherapy the focus is on pathology, however, and Freudian writers would naturally receive more attention.

The explanation for social work's being less Freudian on the level of practice than on the personality theory level seems to be quite different, however. As suggested in the introduction, orthodox psychoanalytic theory explains behavior predominantly on the unconscious level and attributes the causes of behavior and psychological problems to deeply repressed conflicts, treatment of which, for the most part, falls outside the accepted function of the caseworker.

The fact that Vaillen found 75% of the personality books used in social work were orthodox Freudian and this study only 44%, may simply reflect the realization that social work cannot apply directly what they learn in personality courses.
(Human Growth and Behavior)

Another explanation may be equally valid. That is, social work's refusal to identify what they do as psychotherapy. (24) Most of the radical authors used by psychology consider that much of casework is psychotherapy which might lead social work to further re-examine its position in relation to this issue. Two explanations are usually offered for disassociating psy-

(24) Austin, Lucille M., "Relationship Between Family Agencies and Mental Health Clinics", *Social Casework*, Vol. 36, 1955, p. 57.

chotherapy from social work: that traditionally only persons with medical training can treat "sick" persons and if social work called what they do psychotherapy they would invoke the wrath of the medical profession. This may have some basis in fact, but psychology is not afraid to contest the sacred right of the medical profession to help persons with psychological problems.

The other explanation for avoiding the term psychotherapy is the desire to be a unique and differentiated profession.

If these explanations contain some elements that are valid the profession of social work may be deprived of some of the gains of cross-fertilization.

This study showed that we use books classified as dealing with psychotherapy 13% of the time. This is the average extent of their use of the 60 schools comprising the study. A few schools use books on psychotherapy quite extensively, but most use them hardly at all. In fact, one school made up about 1/3 of all of the references to these books.

Nearly all of the books used by psychology are particularly appropriate in that whether the author is Freudian or not, the traditional method of psychoanalysis is sufficiently altered not only to be compatible with social work's means or methods, but also social work's ends or goals.

As a matter of fact, one of the most popular books in psychology, Selby's Principles for Psychotherapists, was written by a social work faculty member, probably a lecturing psychiatrist, yet was only mentioned by one school of social work. Harper's Psychopathology and Psychotherapy: 26 Systems, is

written by a psychologist who worked as a social worker for several years but is apparently unknown to social work.

Aside from any value this study has in describing similarities and differences between psychology and social work, I will consider it worthwhile if it serves to motivate or even spur social workers to take more advantage of the well articulated descriptions of therapeutic practice which can be so easily incorporated into our existing body of practice knowledge.

The 10 most popular books in psychology were evaluated in terms of their usefulness for social workers. Only Freud and Allen were assigned a value of fair. Menninger, Dollard and Rogers were good, and Colby, Alexander and French, Fromm-Reichmann, Wloborg and Sullivan were considered excellently suited for social work's present frame of reference as well as were many others.

APPENDIX T

Facsimile of Questionnaire Sent to Departments of Psychology
and Schools of Social Work

Quantitative Concerning Methods Employed in Computing, Estimating, and on Special Examples

Instructions and Applications

This project is a descriptive study of what is taught in methods courses in several of the schools of education of the state of Massachusetts, as indicated by course titles and readings. The person filling out the questionnaire should be the individual who taught the appropriate course in either department or school.

We would appreciate your cooperation in returning this completed article no later than February 1, 1951.

We would appreciate it if you would enclose copies of the course outline, reading lists, etc., which you distribute to your students.

APPENDIX II

Facsimile of Letter Enclosed With Questionnaire

Michigan State University East Lansing

College of Business and Public Service
School of Social Work

January 6, 1961

Gentlemen:

Mr. James Richland, a second-year graduate student at this school, is conducting a study of similarities and differences between social casework as practiced by social workers, and counseling or psychiatry as practiced by clinical psychologists.

Part of the study is concerned with the major publications relating to these methods of offering help, and with the extent to which the publications are used by schools of social work and departments of psychology. Toward this end, he is enclosing a questionnaire to be completed and returned in the enclosed stamped envelope.

If you wish a copy of the summarized findings, please indicate on the questionnaire. No person, school or department will be identified in either the full report or the summary.

The school is pleased to endorse the study and to seek, appreciatively, your help in its completion.

Sincerely yours,

Gordon J. Alfridge
Director
