ABSTRACT

COMPARISON OF VIBRATION RECORDING PARAMETERS ON POWER DENSITY SPECTRUMS

By

Sukasem Sittipod

The variability that exists in the memory and the programmed recording parameters in various types of data recorders has not been well defined. This study investigated the effect of these differences on the final Power Spectrum Density (PSD) generated by the Environmental Data Recorders (EDR).

Random vibration levels from both an electro-hydraulic vibration table and a 40-foot truck shipment were measured using two types of EDRs. The PSD levels, both numerical and graphical, developed from various recording control parameters were compared.

In the laboratory test, the Grms in PSD results from both EDRs using either the same or different recording parameters did not show significant difference from the input PSD level in accordance with the ASTM D4728. In the actual truck shipment tests, the PSD results showed differences between the total Grms from the EDR with Sliding Window Overwrite[®] recording mode and the EDR with regular Overwrite recording mode in all tests. Although there were differences among the numerical PSD results from the two EDRs, there were similarities in the PSD plot shape in graphical PSD results.

To my parent, Rein and Junsom,
my wife, Jarunya,
my daughters, Suchaya and Sichaya
for their endless love and support

ACKNOWLEDGMENTS

I would like to express my deep sense of gratitude to my major professor Dr. S. Paul Singh for his patient, assistance and expert guidance throughout my thesis research. I would like to thank Dr. Gary Burgess and Dr. Julian Lee for their support and serving on my committee.

I would like to acknowledge my appreciation to Mr. Gregory D. Hoshal President of Instrument Technology (IST) Incorporated of Okemos, Michigan. Mr. Hoshal supported this thesis research not only by giving his invaluable time and guidance into the instrumentation but also provided main equipment include two Environmental Data Recorders with manuals, RS-232 interface cables, Dynamax software and full technical support. I also want to thanks Mr. Daniel R Burk, IST engineer, for the training on EDR and his technical support.

Also, I would like to thanks Michigan State University Food Store for allowing its truck to be used during the shipment test.

Grateful acknowledges is also extended to the Royal Thai Government, Ministry of University Affair, Kasetsart University, and Department of Packaging Technology, Thailand for the opportunity and financial they have provided through out my program of study.

Finally my thanks also go to all friends at School of Packaging especially Jay Singh for his help during my research.

CHAPTER 1: INTRODUCTION

1.1. General outlook

The distribution environments such as shock and vibration encountered by packages during storage, handling and transportation can cause serious and immeasurable product damage. The complicated dynamic loading and the random nature of transport hazards make it difficult to experimentally determine the optimum protective packaging.

Historically, studies of test shipments and related measurement projects in the package design process has been very labor intensive. Before the availability of mechanical and/or electronic monitoring devices, environmental measurement was often conduct through simple observations. Engineers would observe handling and dropping of packages and extrapolate such observations and estimate frequencies of drop heights, impact severity, etc. Investigators would also ride along with truck or rail shipments and observe package dynamics under vibratory excitation (Hoshal, G. and Pease, T. 1994)

In the late 1950s to early 1960s mechanical recording devices began to be used in transportation monitoring. Such devices ranged from a simple friction mechanism such as a small arrow wedge in a hollow cylinder to a mechanical paper chart recorder driven by spring or clock-wound movement for self operation up to a period of time. Practically the only so-called “self-contained” instruments were recently developed and commercially available, i.e., those instruments whose components are confined to a single, easily portable case because this type of instrument combines the advantages of portability and ease of operation.

The major evolution of electronic recorders for distribution measurement has started since Endevco Corporation introduced the TEMARS (Transportation Environments Measurement and Recording System) in the late 1960s. The device utilized not only a threshold triggered digital recording from a built-in, signal-conditioned, piezo-resistive tri-axial accelerometer but also stored the actual data with time stamping in digital format on magnetic tape. Until early 1980s, technology was driving the size and weight of environmental recorders down from the 70-lb TEMARS to the 40-lb A-700 of Geotech Instruments. By mid 1980s the DHR-1, which was introduced by Dallas Instruments, weighed only 10lb and had a size of 6 x 6 inches. The DHR-1 was one of the first devices of its kind to allow recorder setup and data upload to a PC via direct RS-232 interface. Shortly after that, Lansmont Corporation introduced the DHT-1000 environmental recorder with a weight of 4-lb and a size of 5 x 7 x 3 inches. The recorder was exclusively designed for measuring package drop height with recording capacity up to 999 drop-height readings.

In the past few years portable environmental data recorder units using solid state accelerometers have had the same important design guidelines. These include the recorder be small, light weight, and self-contained for field use. It is also recommended that the device is high-impact strength, low frequency response as well as capable of tri-axial accelerometer measurement.

At the present time, the environmental recorders range in size from several ounces to several pounds, including sensors, power supply, and data storage. Such devices offer extended onboard data storage allowing recording of numerous data, orders of magnitude greater than their prototype a decade before.

1.2. Environmental Data Recorder

In this particular study, the Environmental Data Recorders (EDR) that have been developed since 1987 by the Instrumented Sensor Technology (IST), Inc. in Okemos, Michigan were used. The EDR combines a piezo-resistive tri-axial accelerometer with a microcomputer system to allow remote unattended recording of shock and vibration over extended periods of time. The accelerometer consists of three ultra lightweight sensors, which are mounted within the recording unit case made from polyurethane resin (Figure 1).

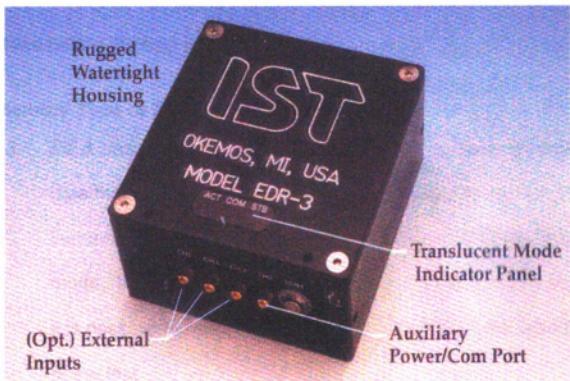

Figure 1:Environmental Data Recorder (EDR)

The recorder comes with an operating software package and is programmed via a standard RS-232 interface with a host personal computer. The software package has two basic functions: recording shock, vibration, and temperature database on user-selected parameters, and providing a medium for retrieving and analyzing recorded data.

The principle operation of the EDR depends upon digital sampling which is the process of converting continuous wave form to a series of discretely quantified time samples. The number of samples taken per unit time is called the sample frequency or sample rate. In order to get a statistical accurate result in the characterization of specific shock and vibration environments during a single field-test, the extensive data collection needs to be done. However during most test shipments especially for measuring the random vibration the digital recorders often do not have enough data memory to record the entire vibration time history of the shipment. In order to solve this problem the user has to specify the type of memory or select the method for managing the recorded data, in case its memory should become filled before the field test is completed.

1.3. Memory Type or Memory Modes for the EDR

1.3.1 *Fill & Stop memory mode.* This first option results in recording all data that satisfied the trigger requirement until the memory in the instrument is full and automatically changes the unit into standby mode. In some instances this may be acceptable, but in many cases it is possible to miss valuable field data if memory fills before the end of the test.

1.3.2 *Overwrite memory mode.* Once the memory fills, the recording process does not stop. The new data may overwrite or replace the previously record data depending upon an amplitude ranking criteria. Hoshal (1998) explained how this method works in step by step as follow:

- i. Event recording starts for events 1, 2, 3, ... up to M events during the test. During the recording of each event the recorder computes amplitude values a_1, a_2, a_3, \dots up to a_m . Appropriate amplitude measures are usually either a Gpeak or a Grms for each of the individual M record events.
- ii. The $M+1$ event is captured. The a_{m+1} is computed.
- iii. A check of event amplitude is then performed: If a_{m+1} is less than $a_1, a_2, a_3, \dots a_m$ then the ($M+1$) event is discarded. If a_{m+1} is greater than $a_1, a_2, a_3, \dots a_m$ then event ($M+1$) replaces the event that has the lowest amplitude.

By using this option the recorder accumulates events which have the largest energy content, or worst case, during the field test. However the limitation for using this mode is a maximum number of events that has to be determined base upon the amount of memory storage available in the recorder so that the total amount of events may fit within available memory.

- 1.3.3 *Sliding Window Overwrite memory mode.* This is an advanced version of overwrite memory mode with an additional time criteria called “windows”. After the memory is filled, instead of a new data overwriting a previous recorded data event on a one by one basis, a group of previous recorded data within a given amount of time frame (window) can be overwritten by the same number of new larger events. In this mode time has to be partitioned into bins called windows prior to the test and only a preset number of events are saved within each time window.

Sliding window overwrite ensures that a particularly severe section of acceleration will not overwrite all the lower level events in the memory. This mode allows a user to break up the test shipment into independent time periods where the random vibration characteristics may change significantly over time. When applied this mode to random vibration measurement, the time period analysis of Power Spectral Density (PSD) of each individual profile will give a better result than the single PSD profile averaging data over the entire test period. The result from Sliding Window Overwrite recording mode would lead to more realistic PSD-based simulations particularly if transport modes or condition change from time to time during the measurement period.

1.4 Power Spectral Density (PSD)

In random vibration, the most common approach to analyze the recorded signal is to decompose it into its component frequencies and amplitudes. Whereas it is virtually impossible to identify a specific instant of a single amplitude or peak of the signal, the accepted procedure is to sample the filtered signal at preset regular time intervals. For this purpose the digital bandpass filter or tuner is needed to select a specific frequency range to pass through and exclude all others. After a large number of samples are taken, statistical analysis of a vibration time-history is carried out to determine the characteristics of the vibration.

In general, three coordinates are necessary to describe a vibration time-history: (1) the magnitude of the vibration; (2) the variation of magnitude with frequency; and (3) the variation of the magnitude of the vibration at a particular

frequency as a function of time (Harris 1995). Figure 2 shows the relationship among these three vibration criteria.

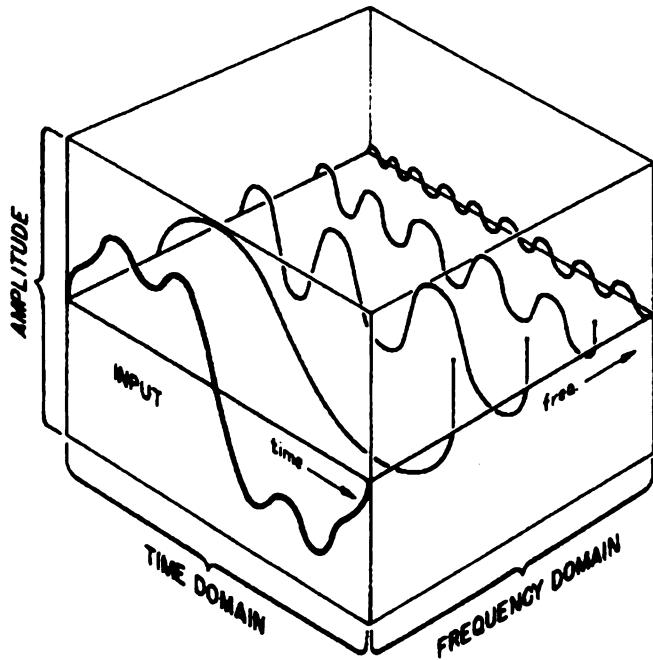

Figure 2: Vibration Time History Concept.

By using the typical vibration waveforms or time-history plots that are known as line spectrum or discrete frequency spectrum (Fourier series), and a statistical analysis, series of PSD are determined to characterize the variation of the vibration magnitude with frequency.

PSD is defined as the limiting value of the mean square response of an ideal bandpass filter, divided by the bandwidth of the filter, as the bandwidth of the filter approaches zero. In other words the power density level at any frequency is the square of the standard deviation of a random sampling of the vibration magnitude. In this case it is the acceleration amplitude (G value), taken from the recorded

random vibration signal after it has passed through a pre-specified bandwidth tuner.

The standard deviation of G's for N samples is defined by the following equation:

$$S = \sqrt{\frac{\sum_{i=1}^N (G_i - \text{mean})^2}{N-1}}$$

Since the mean is zero and N is large, the standard deviation becomes

$$S = \sqrt{\frac{1}{N} \sum_{i=1}^N G_i^2} = Grms \ (N \rightarrow \infty)$$

Grms = Root Mean Square Acceleration

Once the RMS G is defined, the square of its value is divided by the bandwidth of the tuner to get the power density:

$$\text{Power Density} = \frac{(Grms)^2}{BW}$$

The reason for dividing $(Grms)^2$ by the bandwidth is to remove the influence of the tuner on the results.

Power density for respective frequency bands are then graphed to get what is called PSD plot. The PSD plot has the same frequency and amplitude as the original recording but occurs in a different order.

Figure 3 illustrates a plot of power spectral density as a function of frequency obtained from spectral analysis of a random function.

According to the American Society for Testing and Materials (ASTM) test methods for random vibration testing of shipping containers, ASTM D 4728-91, PSD data is required as an input to operate the vibration test machines. Even though PSD data could be derived from actual field measurements, it must be accurately recorded with equipment having adequate frequency response to

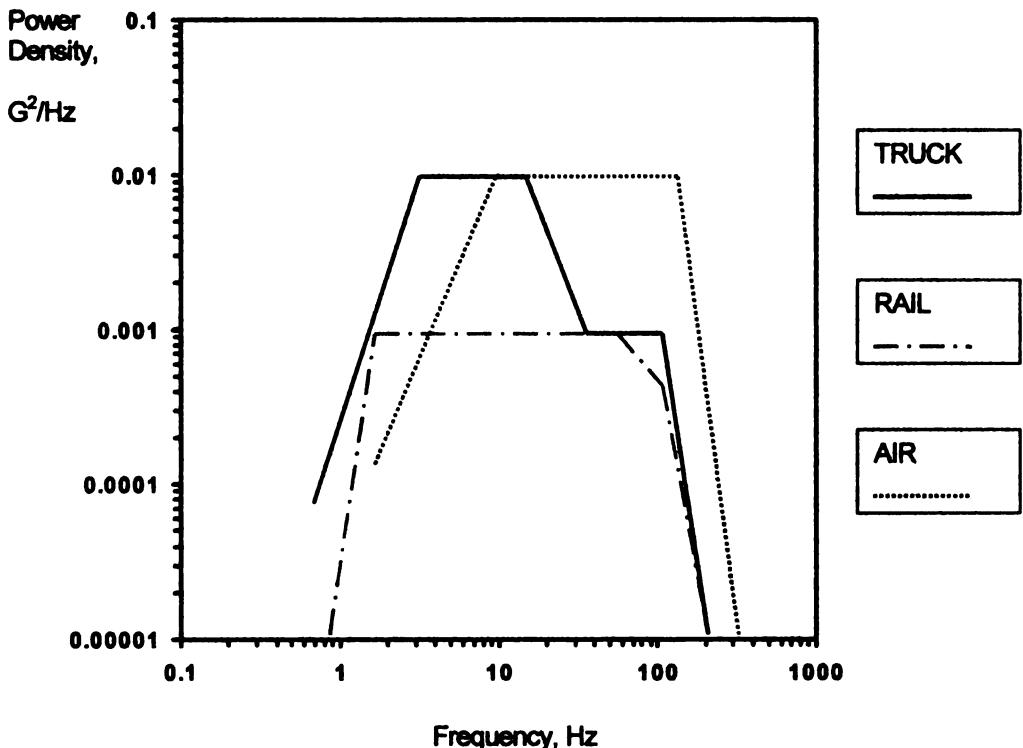

Figure 3: Commercial Transport Random Vibration Spectral Summary

prevent attenuation of the acceleration energy levels. The other source of PSD data is the published data, which depends on typical transport vehicles under representative conditions of speed, load, suspension, road surfaces, etc

1.5 Previous Studies

In order to examine the distribution environment and monitor potentially damaging dynamic events, the data recording units have been placed in trailers during shipping. The field data is then analyzed to generate the PSD plot to use in a laboratory environment to reproduce the field severity. As a result, packaging

engineers can carefully develop packaging systems to reduce the chances of distribution damage.

Fell (1995) studied the correlation between transportation time and vibration table time using the EDR as the vibration environment recorder. She found that the correlation is not an equal one to one and to determine an actual correlation is very complicated. In addition using the EDR was slightly in error because of the difficulty in the RCPs (recording control parameters) programming. After switching between some parameters in the RCPs of the EDR from the actual and simulated shipments, she concluded, "changing the RCPs has little effect on the PSD plot". Her final conclusion stated that attempting to re-create the actual transportation environment on the simulated vibration table is a "very difficult task" but the need for simulating the distribution environments is a "tremendous one".

Languet (1997) also studied the correlation between two types of EDR for the same simulation time as a part of her research and the conclusion indicated that there was no significant difference between the PSD plots from the different EDRs. Based on her result, she concluded that the choice of RCPs when using any EDR does not significantly influence the PSD plot.

The following recent studies are recommended by ASTM for random vibration testing of shipping containers if specific data is not available:

- i. An Assessment of the Common Carrier Shipping Environment by Ostrem, F.E., and Godshall, W. D. (1979).
- ii. Comparison Between Lateral, Longitudinal, and Vertical Vibration Levels in Commercial Truck Shipments by Singh, S.P., Antle, J. R., and Burgess, G. G. (1992).

- iii. Vibration Levels in Commercial Truck Shipments as a Function of Suspension and Payload by Singh, S. P. and Marcondes, J. (1992).
- iv. Study of the Shock and Vibration Environment in Boxcars by Association of American Railroads (1992).
- v. A Technical Summary of the Intermodal Environment Study by Association of American Railroads (1991).

1.6 Objective

Due to the variability that exists in the memory and programming parameters in various types of data recorders, this study investigated the effect of these differences on the final PSD's that are generated using these recorders.

Specifically the objective of this thesis was to measure vibration levels in truck shipments using different type of EDR's and compare the PSD levels developed using different recording control parameters.

CHAPTER 2: EXPERIMENTAL DESIGN

2.1 Equipment

2.1.1 Vibration data recorder and software

Two types of the EDRs were used in this study; (1) EDR 3: Model no. EDR-3-10 with the size of 4.2 x 4.4 x 2.2 inches, and a weight of 2.2 lb and had 3.5 Mb data memory onboard. Four C-type Alkaline batteries power this recorder for 30-40 days in the temperature ranging from 1 to 60 °C. (2) EDR 4: Model no. EDR-4-50 with the size of 5.7 x 5.2 x 2.9 inches, weighed 4.9 lb, and had 24 Mb data memory. Four D-type Alkaline batteries power this recorder for 60 days in the temperature ranging from -40 to 70 °C (Figure 4).

Figure 4: EDR 3 (left) and EDR 4 (right) are connected to a PC via RS 232 interface to setup the RCP prior to the vibration test.

2.2.2 Truck - Trailer System

Figure 5: Truck used during the study

Truck Information:

Owner: Michigan State University Food Store

Maker: GMC

Type: 40-ft trailer

Model: Double Axle

Suspension system: Leaf Spring

EDR mounting position: On the trailer floor at the rear end (1ft from end)

Speed: Average 65 mph

Road Surface: Interstate Highway (Concrete and Paved), and some
inner city (Lansing – Detroit)

2.2.3 Electro-hydraulic Vibration Table

Figure 6: Lansmont Vibration Table

Vibration Table Information:

Owner: School of Packaging, Michigan State University

Manufacturer: Lansmont Corporation, Monterey, CA

Table size: 60 x 60 inches platform

Model number: 10000 -10

Controller: Touch Screen Monitor System Station

2.3 Experimental Procedures

The initial part of this study was to use the electro-hydraulic vibration table as a vibration source for the comparison study of different recording control parameters of both EDRs. For the second part the test was done using the 40-ft truck (Figure 5) without any load journeyed from East Lansing to Detroit and the return trip with a fully loaded truck.

2.3.1. *Experimental Setup*

Experimental setup of this study is shown in Table 1.

Test No.	Place of study	RCP code*	EDR-3	EDR-4
1	MSU	A	X	X
2	MSU	B	X	X
3	East Lansing -Detroit.	C	X	X
4	Detroit - East Lansing	C	X	X
5	East Lansing -Detroit.	D	X	X
6	Detroit -East Lansing	D	X	X

*Detail of each RCP code is shown in Table 2.

Table 1: Experimental Setup

2.3.2 *Experimental Procedure*

2.3.2.1 The electro-hydraulic vibration table (Shock and Vibration lab, School of Packaging, MSU) was used.

- i. Both EDR3 and EDR4 were set with the same RCP (code A) except the recording mode of the EDR4 was the sliding window overwrite mode while that of the EDR 3 was the overwrite mode.
- ii. Both EDR3 and EDR4 were activated and mounted on the center of the vibration table with the same orientation using an aluminum bracket as shown in Figure 7.

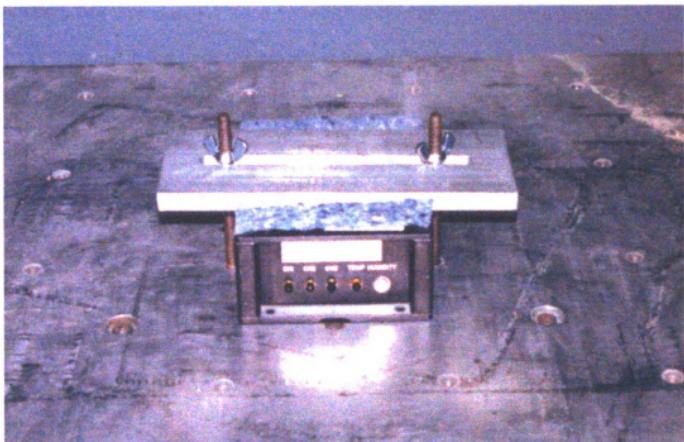

Figure 7: Mounted EDR on the vibration table

- iii. The vibration table was subjected to the known Power Density Spectrums as recommended in ASTM D4728 Assurance Level II which include:
 1. Truck Mode: Grms = 0.52 15 minutes
 2. Rail Mode: Grms = 0.29 15 minutes
 3. Air Mode: Grms = 1.09 15 minutes
- iv. After the vibration test, each recorded data was downloaded to a PC and then analyzed by the DynaMax™ software.

- v. The same test was redone with the same procedure except the EDR3 and EDR4 were reset with the RCP code B.

2.3.2.2 MSU Truck Shipments:

- i. Both EDR3 and EDR4 were set with the same RCP (code C) except the recording mode of the EDR4 was the sliding window overwrite mode while that of the EDR 3 was the overwrite mode.
- ii. Both EDR3 and EDR4 were activated and mounted side by side with the same orientation in the trailer as shown in Figure 8.

Figure 8: Mounted EDRs on the empty truck floor

- iii. The MSU truck outbound journey started from MSU food stores, East Lansing to the Detroit Produce Terminal, Detroit. At the destination place, recorded data from each EDR was downloaded to a PC.
- iv. Both EDR3 and EDR4 were reset with the same RCP (code C) except the recording mode of the EDR4 was the sliding window overwrite mode while that of the EDR 3 was the overwrite mode.

- v. Both EDR3 and EDR4 were activated and mounted side by side with the same orientation on the loaded truck floor as shown in Figure 9.

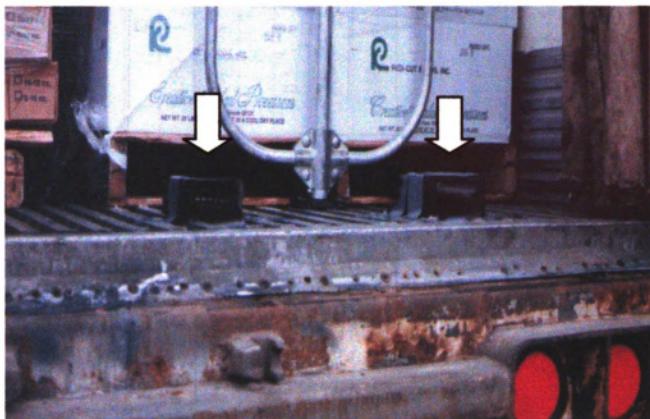

Figure 9: Mounted EDRs on the loaded truck floor

- vi. The fully loaded MSU truck return journey started from Eastern Market, Detroit to MSU food stores, East Lansing. Each trip was approximately 2 hours.
- vii. At the destination place, recorded data from each EDR was downloaded to a PC and then analyzed by the DynaMax™ software.
- viii. The same test, from i. to vii., was redone with the same procedure except the EDR3 and EDR4 were reset with the RCP code D.

Note: The EDR3 recorders use a built in low pass filter. However the EDR4 has a digital filter that can be selected in the RCP. In all tests conducted a 255 Hz filter was selected for the EDR4. It should be noted that the filter frequency for both EDRs should be high enough to not cause aliasing in the data analysis. A low filter frequency would delete some of the data and could produce erroneous results.

2.3.3 RCP Setting for EDR3 and EDR4

Four RCPs, A, B, C, D setting were programmed into both EDR prior to the test via Dynamax™ program from a PC.

Table 2: RCP setting for EDR 3 and EDR 4

RCP Code	A	B	C	D
Recorder Type	EDR3	EDR4	EDR3	EDR4
Sampling Rate(Samples/sec)	500	500	500	500
Low pass filter (Hz)	-	255	-	255
Trigger Level (g)	0.5	0.5	0.2	0.2
Pre-trigger Length (samples)	300	300	300	512
Post-trigger Length (samples)	724	724	724	512
Maximum Event Length (samples)	1024	1024	1024	1024
Recording Mode	Overwrite	Sliding window overwrite	Sliding window overwrite	Sliding window overwrite
Overwrite Limit (events/window)	800	800	800	830
Sliding Window Parameters				
Time per Window (min.)	-	15	-	15
Maximum no. of Window	-	3	-	3

CHAPTER 3: DATA AND RESULTS

The data collected from different RCP settings and experimental setup were analyzed in terms of PSD plot with total Root Mean Square of the vertical acceleration level (Grms), mean-G, peak-G, maximum and minimum level of G. All the detail results in form of event tables are shown in the Appendix. The summary of the relevant results are presented and discussed in this chapter.

3.1 The whole data was analyzed as they are in a single frame window using a typical data processing method which is shown in Appendix.. The numerical summary is shown in Table 3 and the graphical results are shown in Figure 10 to 21.

Test No.	Location & Trip	RCP code	EDR 3			EDR 4		
			Total Grms	Max. PSD g ² /Hz	Freq. at max. PSD, Hz	Total Grms	Max. PSD g ² /Hz	Freq. at max. PSD, Hz
1	Vibration Table	A	0.7852	.0147	10.00	0.6735	.0088	11.16
2	Vibration Table	B	0.7917	.0141	11.00	0.5658	.0083	11.16
3	East Lansing-Detroit	C	0.4497	.0735	4.39	0.2982	.0267	4.88
4	Detroit-East Lansing	C	0.3821	.0621	4.39	0.3204	.0120	4.88
5	East Lansing-Detroit	D	0.4706	.0666	4.39	0.2995	.0195	5.62
6	Detroit-East Lansing	D	0.4095	.0245	3.91	0.2605	.0039	4.69

Table 3: Comparison of PSD Results from Different RCPs of two EDR

As the analysis was made on the single frame (window) basis, in the first two tests on the vibration table, there is only a slightly different between the average total Grms from the two EDRs (EDR-3 average = 0.79 g and EDR- 4 average = 0.62 g). From graphical results both EDRs give similar shape of the PSD plot and have the peak PSD at the same frequency at 10 Hz.

While the total Grms from EDR 3 in test no. 1 and test no. 2, which has different RCP, are nearly the same Grms at 0.79 g, the total Grms from EDR 4 in Test no.1 is significantly higher than that in Test no.2.

In the real transportation test, the result shows differences among the total Grms from the two EDRs in all four tests. Whereas there are comparable results from two test of the same EDR using two different RCPs (Test no.3 and Test no.5 or Test no.4 and Test no.6); there are significant differences between the two test results from the same EDR using the same RCP on different truckload (test no3 and no4 or test no5 and no6).

When comparing the shape of the PSD plot there are similarities between the plot from the two EDR on the same test and the location of the PSD peaks are also nearly in the same range of frequency in all tests.

Graphical Results: PSD Plot from the data of EDR3 and EDR4

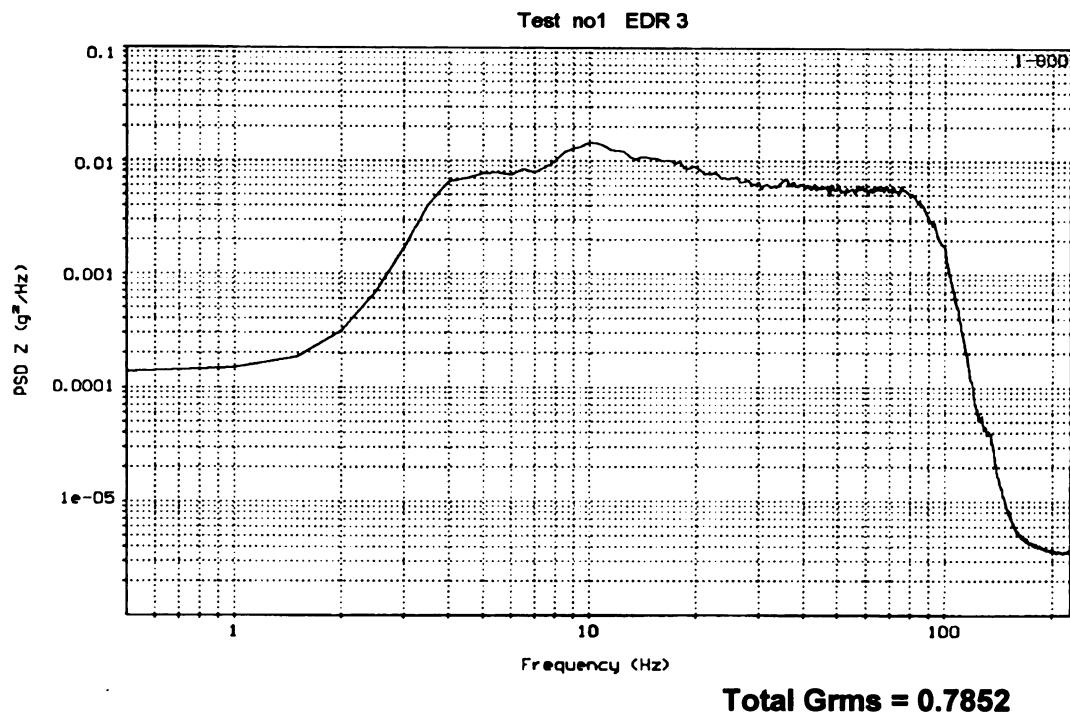

Figure 10: PSD Plot from Test no. 1 EDR 3 (vibration table, RCP: A)

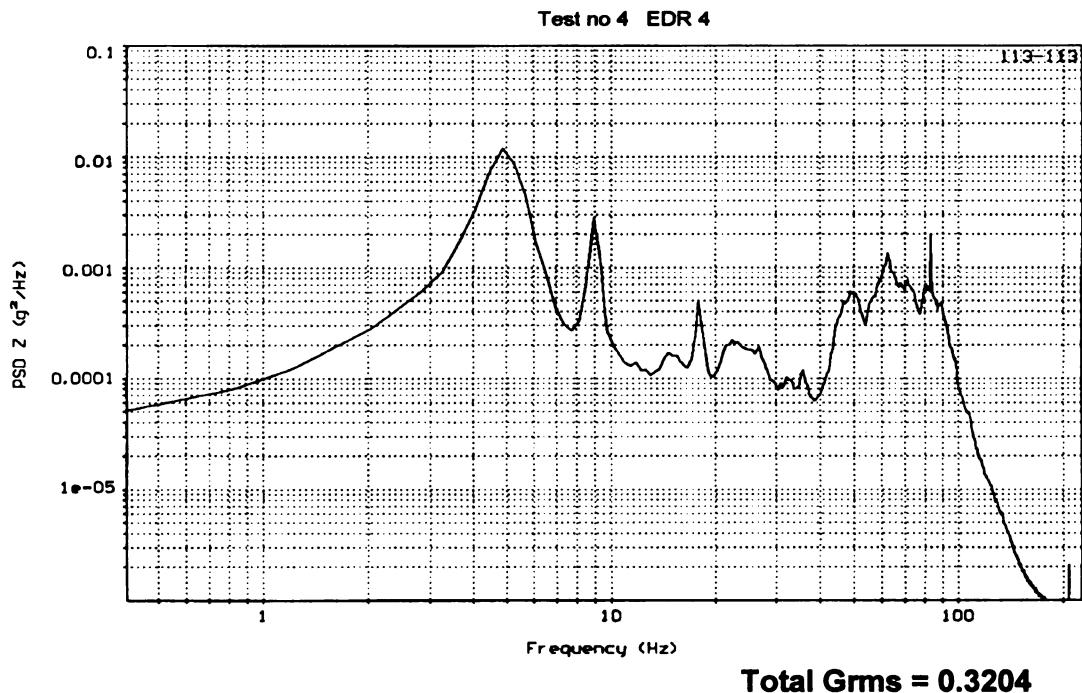

Figure 17: PSD Plot from Test no. 4 EDR 4 (Detroit -East Lansing ; RCP: C)

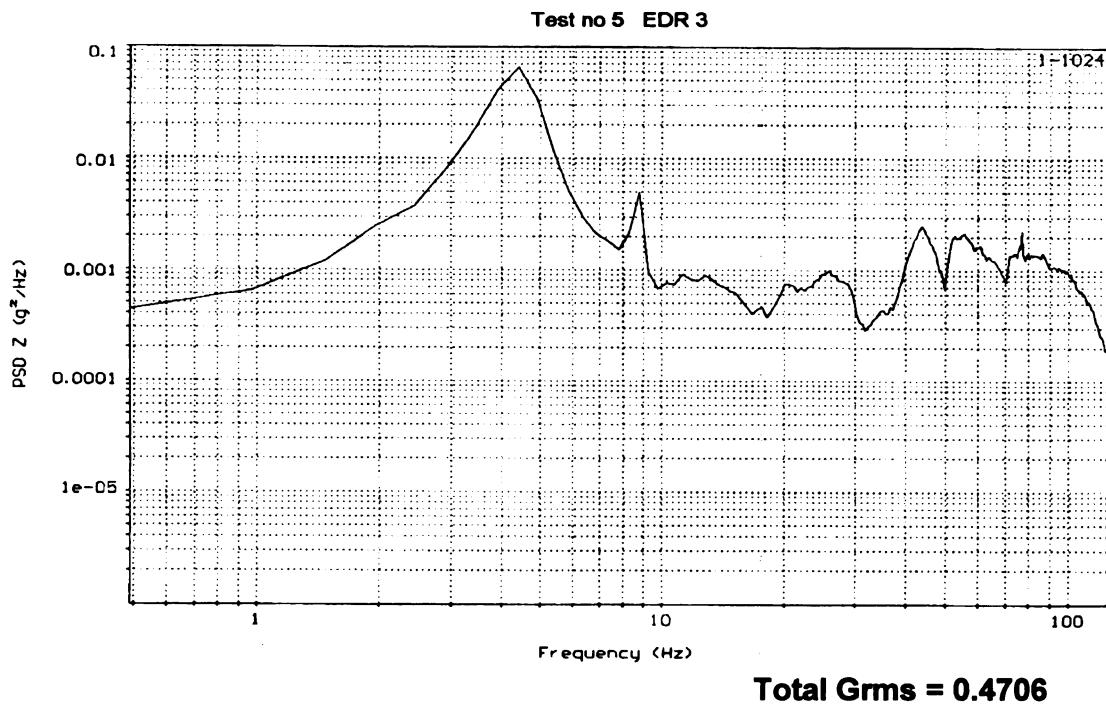

Figure 18: PSD Plot from Test no. 5 EDR 3 (East Lansing - Detroit ; RCP: D)

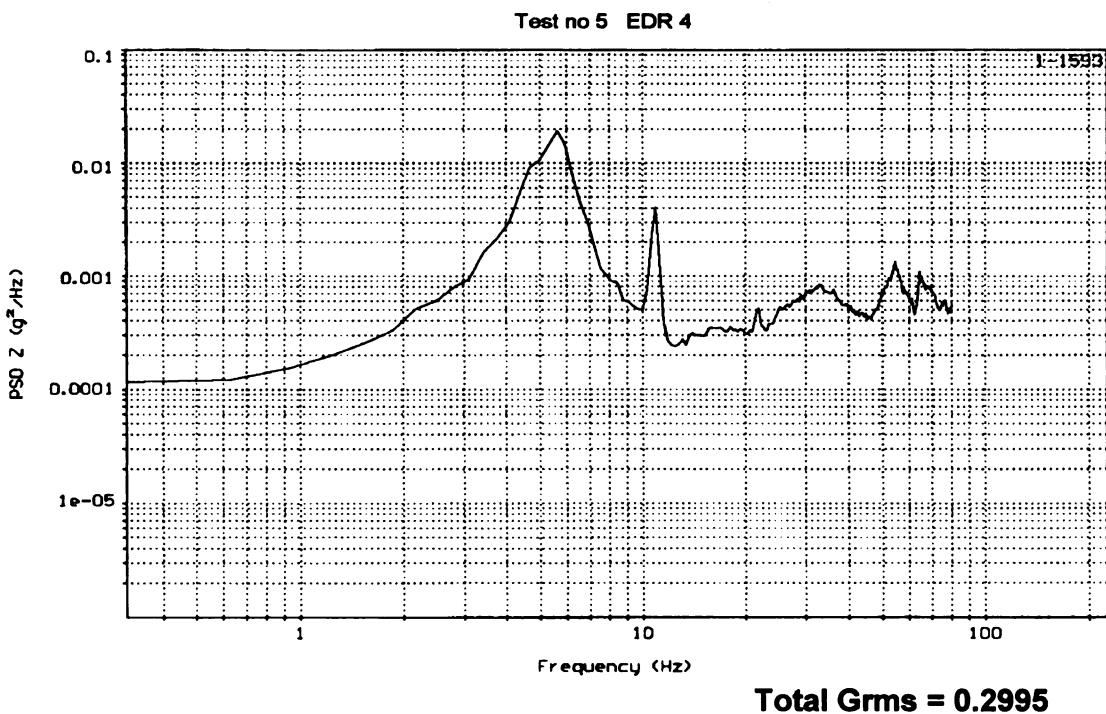

Figure 19: PSD Plot from Test no. 5 EDR 4 (East Lansing - Detroit ; RCP: D)

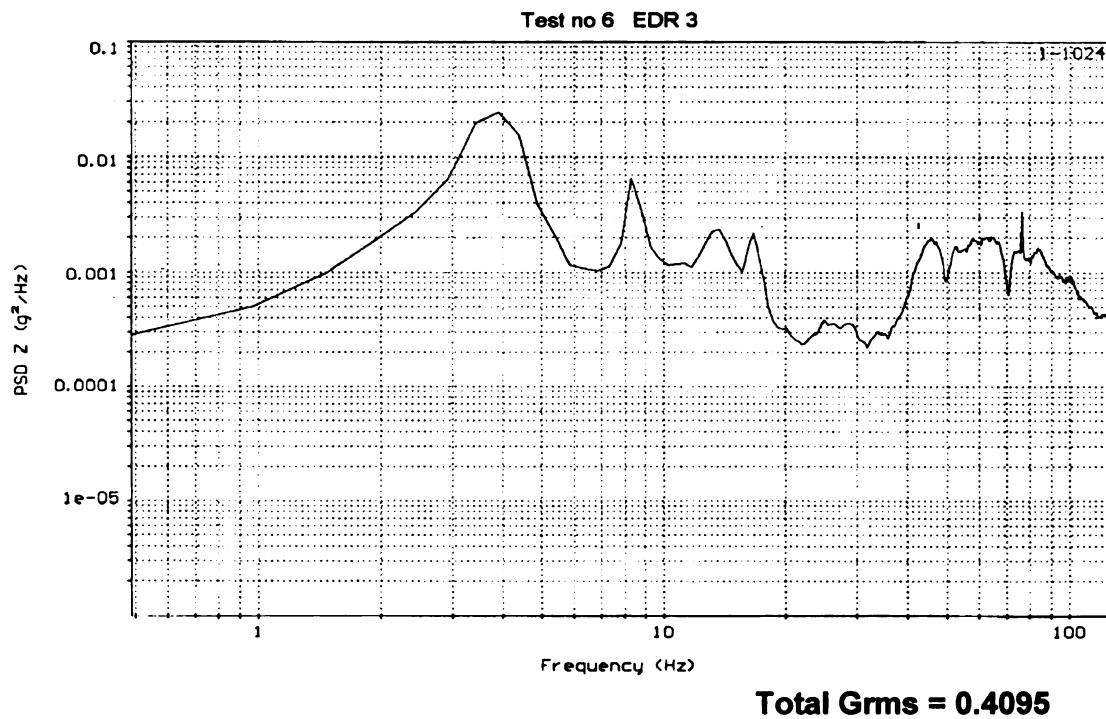

Figure 20: PSD Plot from Test no. 6 EDR 3 (Detroit -East Lansing; RCP: D)

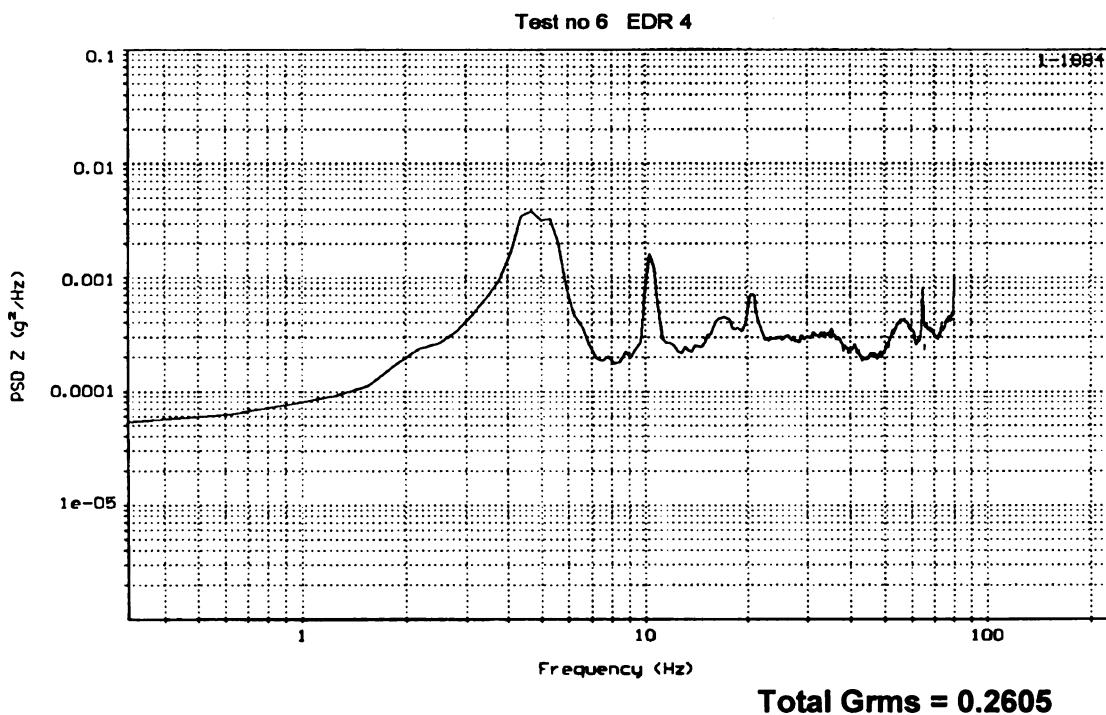

Figure 21: PSD Plot from Test no. 6 EDR 4 (Detroit -East Lansing; RCP: D)

3.2 The whole data was also analyzed in multiple frame windows using a time separation data processing method. An individual PSD can be computed from each respective set of vibration time history, which is shown in the Appendices.

3.2.1 From the first two tests on vibration table, the 15 minutes time separation was used according to the three different vibration table inputs: started with fifteen minutes on Truck Spectrum ($Grms = 0.52$). The next fifteen minutes on Rail Spectrum ($Grms = 0.29$) and the last fifteen minutes on Air Spectrum ($Grms = 1.09$). Therefore three separation time frames were analyzed. The numerical summary result is shown in Table 4, and the graphical results are shown in Figure 21, 22, 23 and 24.

Test No.	Test Location	RCP code	EDR type	Grms		
				part I 0-15 min	part II 15-30 min	part III 30-45 min
1	Vibration Table	A	EDR 3	0.5543	-	0.9274
			EDR 4	0.5293	0.2887	0.9989
2	Vibration Table	B	EDR 3	0.5555	-	0.9381
			EDR 4	0.5015	0.2576	0.8007

Table 4: Comparison of PSD Results from Different RCPs of two EDRs when analyzed using 15 minutes of three time frame window.

From the EDR 3 results in Table 4 there are only two parts of the data presented in the preset time interval which are the first and the third window and there is no significant difference between the numerical result from the two tests (Test no.1 and Test no.2). The average Grms from the first window (0.5549 g) and the third window (0.9328 g), are comparable with the input Grms which are 0.52 g for the first (Truck) mode and 1.09 g for the third (Air) mode respectively. One of the input Grms, from rail mode which is as low as 0.29 g, was not present in the result due to the overwrite mode setting in the RCP.

In Figure 22 (a) & (b) and Figure 24 (a) & (b) the PSD plot shape are also very similar with the PSD plot from the truck and the air modes in figure X1.1 of ASTM D 4728.

For the EDR 4, there are data in the entire preset time window as shown in Table 4. The average Grms from the first window from two tests (0.5154 g) is very close to the first input from the 0.52-g of the truck mode. The second and the third window from two tests have the average Grms 0.2732 g and 0.8998 g respectively are also corresponding to the input Grms that are 0.29 g and 1.09 g from the rail and the air mode respectively.

The PSD plot in Figure 23 and 25 (a), (b) and (c) also show similarity with the three input modes of ASTM D4728.

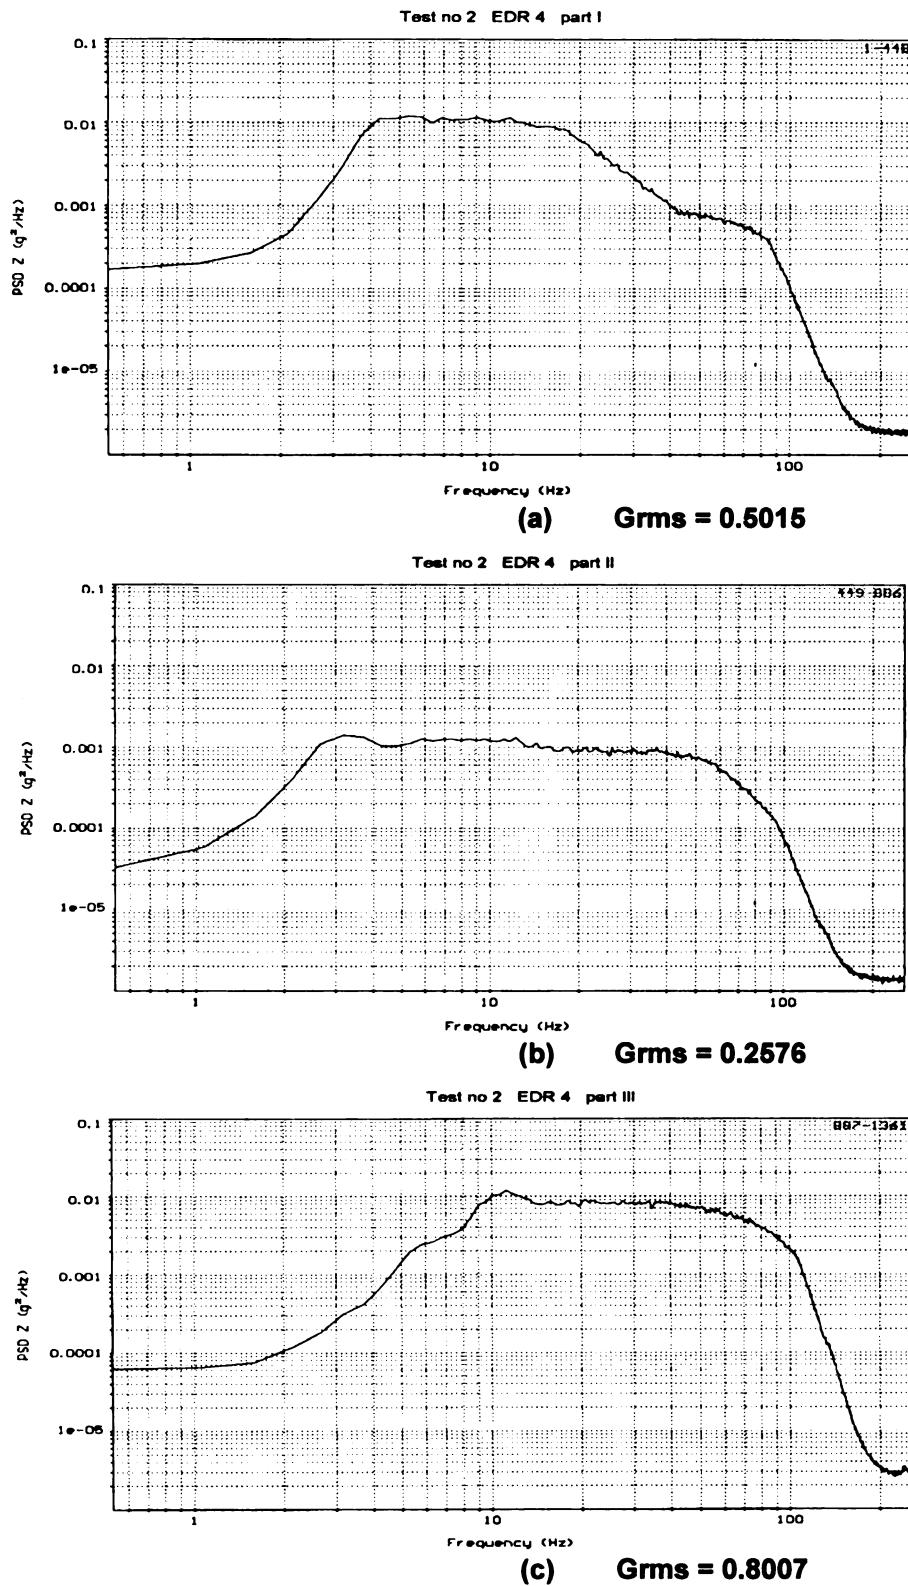

Figure 25(a), (b),and (c): PSD Plot from Test no 2 EDR 4 separated into three windows

3.2.2 For the real shipment tests on the truck, as the travel time for the real shipment test on the truck was approximately 100-120 minutes, the time interval of each window was preset at 30 minutes for four windows. The EDR 3, which has no availability of the sliding window feature, was preset with the Overwrite mode within the entire travel time and should present only one single window as shown in Table5. However, for comparison purpose reason, the time tagged data from EDR3 was analyzed with the same partition time window as it was for the data of the EDR 4 and the numerical results are shown in the brackets. The numerical summary result is shown in Table 5 and the graphical results are shown in Figure 26, 27, 28 and 29.

Test No.	Location & Trip	RCP code	EDR type	Grms			
				part I (0-30min)	part II (31-60min)	part III (61-90min)	part IV (91-120min)
3	East Lansing-Detroit	C	EDR3	0.4497			
				(0.4152)	(0.4390)	(0.4532)	(0.4713)
			EDR4	0.1987	0.2925	0.3499	0.2683
4	Detroit-East Lansing	C	EDR3	0.3821			
				(0.3634)	(0.4222)	(0.3583)	(0.3159)
			EDR4	0.3155	0.3662	0.3360	0.1930

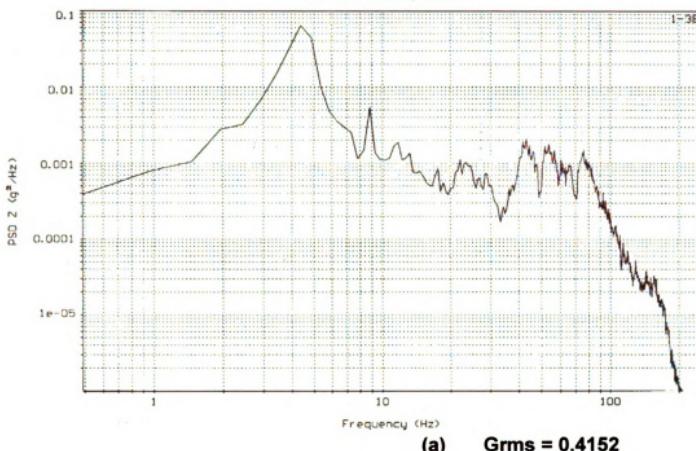

Table 5: Comparison of PSD Results from Different RCPs of two EDRs when analyzed with 30minutes of four time frame windows.

From Table 5 the results from Test no.3, which was the empty load truck, show significant differences between Grms analyzed from EDR3 and EDR4. The

Grms from the first 30-minute of the shipment monitored by EDR4 (0.1987 g) is as low as half of that from EDR3 (0.4152 g) and the highest Grms from EDR4 in the third window (0.3499 g) is also lower than that from EDR3 (0.4532). In Test no.4, which was the fully loaded truck, the differences among the Grms result from both EDR vary from 0.0223 g in the third window to 0.1229 g in the fourth window and all Grms values from EDR4 were lower than that of EDR3.

From graphical result of each window of the two tests that shown in Figure 26 to 29, we see a similarity of the results from the two EDRs. All results show first maximum value of PSD at around the same frequency (4-5 Hz) and the second PSD peak of all plots at frequency around 8-10 Hz. The third PSD peak of all plots is also identified by the frequency range between 40 to 80 Hz.

CHAPTER 4: CONCLUSIONS

Based on the results of this study, the following conclusions were made:

1. When comparing both the numerical and graphical results of the EDR in the laboratory vibration test with the input mode using ASTM D 4728, all of the Grms test results fall within the range of the input Grms.
2. In the truck shipment tests, the results show differences among the total Grms from the two EDR in all tests. Whereas there are comparable results from two tests of the same EDR using different RCPs; there are some noticeable differences between the test results from the other EDR.
3. Both the recorders EDR-3 and EDR-4, when using Overwrite and Sliding Window Overwrite mode, showed similar shaped PSD plots when collecting the same data. Also the peak levels for truck suspension and structural response occurred at the same frequency.
4. Using Sliding Window Overwrite mode enables the EDR to record worst case or high acceleration level data within the preset time frame especially when there is some changes in the acceleration level over time. It is also the only distinctive way to take advantage over the traditional overwrite mode in collecting more representative data.
