A THESIS IN A
COMPARISON OF METHODS FOR DETERMINING THE MOMENT OF INERTIA
OF IRREGULAR BODIES.

Geo. F. Sargent and C. C. Pasney, Experimenters.

AGRICULTURAL COLLEGE:
AUG. 4, 1894.

Now three more methods have been there of the torsion pendulum. The first is graphical processes, and the second is deriving from the center of oscillation as determined by causing the body to oscillate in a pendulum.

The procedure that which as far as I have never been used, to the writer's knowledge, is outlined as follows: The moment of inertia of a solid about any given axis is the summation of the moments of inertia of all the differential volumes composing the solid about their own gravity axis parallel to the axis of reference transferred to this axis of reference. To illustrate, let g be such a differential volume, for simplicity considered as a rectangular prism, let x be at g distance from the axis of reference e .

Let the I_g of g about its gravity axis parallel to e is $1/12mx^2$, and its I_e equals $1/12mx^2$ plus mx^2 . It will be observed that the quantity I_g is small compared with mx^2 , and the error in the present method is that it may be neglected without appreciable error.

In this condition of things, it only remains to hit upon some expedient method of determining the masses, or the weights,

and the location of these differential volumes with respect to the axis in question.

Method 1. The solid used in the experiment of this kind was a leaded and a graphical method was a connecting rod from the main engine and Engine Works, a drawing of which is shown in Figure 1.

The rod was suspended by a differential pulley and a point-rod was used to indicate readings in the scale erected at the end of the firing tank. The overflow caused by each level of the rod was caught in a glass which measured each differential volume in cubic centimeters. All of these points are shown in Figure 2, the accompanying photograph.

The results of the experiments are tabulated in table 1. The first column contains the readings indicated on the scale, the time being taken just as the rod touched the water. Column two contains the thickness of each section in inches. Column three contains the distance of the center of gravity of each section from the gravity axis parallel to the crank pin. The determination of the position of this axis will be hereinafter explained. The gravity axis of each section was considered to be halfway of its thickness. Column four contains the square of the distance of the center of the section from the axis of rotation. Column five contains the number of cubic centimeters in each differential volume. Column six contains the number of cubic inches in each differential volume. Column

seven contains the number of pounds in each differential volume. An appreciable error exists here on account of the failure to take into account the difference in densities between brass and steel. The error is 1.4 percent of the weight of each differential volume with respect to the axis of reference.

The position of the vertical axis of the reel was determined by a spirit level and in LaSalle, and by a method of weighing each end of the reel, knowing the distance between the joints, and also by a graphical method of German origin, described and used by G. H. Hahn, class '08, of Lehigh University, in the *Engineering Laboratory*, etc.

The method from LaSalle was so susceptible of error that the results could not be relied upon. The method by weights located the axis at 34.00 inches from the extreme wrist-pin end of the reel, and the method from the German located it at 34.03 inches from the same end.

Total length of red oval: 30.84 inches.

¹ All volumes in *ERIC* include *ERIC* full text.

Total weight in pounds (derived by calculation) of fish: 101.0

Total weight in pounds (by weighing) equals 101.75.

This value, 64735.43, expresses the π of the rod in terms of circular points, and linear dimensions in inches.

Method II. This is the Gauss method described by Beck. This method is primarily applicable to irregular plane figures, but may be applied to the curvilinear rod in the following described manner: The rod was divided into fifty-seven sections, the center lines of which are shown in plate I, which shows the rod drawn to one half scale. The positions of these center lines of sections are again shown on the line MO in AB, plate III. The area of each section as found by the planimeter from plate II is laid off to a scale of 1 inch equals 1 square inch, on ordinates erected at its own section center. Column 3 of the table hereinafter to be described shows the area of the respective sections as drawn, i. e. at a half scale. Through the ends of these ordinates the curve MNO is drawn. Now if we conceive this curve and base MO to be laid on a plate of unit thickness whose area would be equal to that of the rod and of equivalent distribution. We can treat this as a plane figure and locate the vertical line containing the center of gravity and determine the perpendicular distance from this line. The construction is as follows: Take any ordinate, as MO, and on the point N on the curve draw a line BB', and find the point S where the line joining MO and BB' meets the ordinate MO. At point S on BB' at S and draw a line SS'. R is a point on the line and T of the curve derived curve; in this manner to points of the curves

III and IV are found.

S_1 equals area of the figure III.

S_2 equals the area of the figure IV.

S_3 equals the area of the figure V.

The following relations are true: AB equals $S_1 / S_3 \cdot X$,

where AB is the distance from AA' of the center of gravity, and X is the distance AB .

I_0 equals $S_1 \cdot X^2$.

I_0 equals $S_1 \cdot X^2 - S_1 \cdot X^2$.

Table II, column 1 contains the scale of the drawings.

S_1 equals 303.43

S_2 equals 303.52

S_3 equals 303.54

X equals 11.01 inches.

Using the substitutions in the above equations, I_0 equals 307.33 expressed in volume and inches.

Table II, column 1 contains the number of the section. Column 2 contains the area of the section in square inches. Column 3 contains the thickness of the section in inches. Column 4 contains the volume of the section in cubic inches. Column 5 contains the weight of the section in pounds. Columns 4 and 5 were calculated and entered as a check to the first table. If, then, we ascertain the volume of the rod to be 303 cubic inches, and the weight to be 100.45 pounds.

81	4.00	.00	0.400	.007	
82	4.00	.00	0.400	.007	
83	4.00	.00	0.400	.007	
84	4.00	.00	0.400	.007	
85	4.00	.00	0.400	.007	
86	4.00	.00	0.400	.007	
87	4.00	.00	0.400	.007	
88	4.00	.00	0.400	.007	
89	4.00	.00	0.400	.007	
90	4.00	.00	0.400	.007	

In conclusion, we have only to compare the results of the two methods. In dealing with the data, we find that the results of the digital method are more accurate than those of the graphical method.

The digital method is the most accurate method of dealing with data obtained by digital. The graphical method is the least accurate. Since, in the digital method, of course, the data are more accurate than in the graphical method, the results of the digital method will be more accurate than those of the graphical method.

It is also possible that with more accurate apparatus for digital data, the results would be even more accurate than those of the digital method.

The digital method is the most accurate method of dealing with data, and the results of the digital method are the most accurate. The graphical method is the least accurate method of dealing with data.
