ACKNOWLEDGMENT

The author wishes to express his sincere thanks and appreciation to Professor Harold Hart for his valued guidance and encouragement throughout the course of the entire investigation.

Appreciation is also extended to the Upjohn Company whose Fellowship Program provided personal financial assistance during part of 1958.

PART I

**THE SYNTHESIS AND SOLVOLYSIS OF TRIFLUOROACETATES
OF CERTAIN CYCLOPROPYLCARBINOLS**

INTRODUCTION

Although this thesis is composed of two parts, both are concerned with cyclopropylcarbinyl systems. Each part will be treated separately for the purpose of clarity. The parts are:

PART I: The Synthesis and Solvolysis of Trifluoroacetates of Certain Cyclopropylcarbinyl ~~Systems~~

PART II: The Synthesis and Attempted Thermal Rearrangement of Cyclopropylcarbinyl Phenyl Ether.

INTRODUCTION

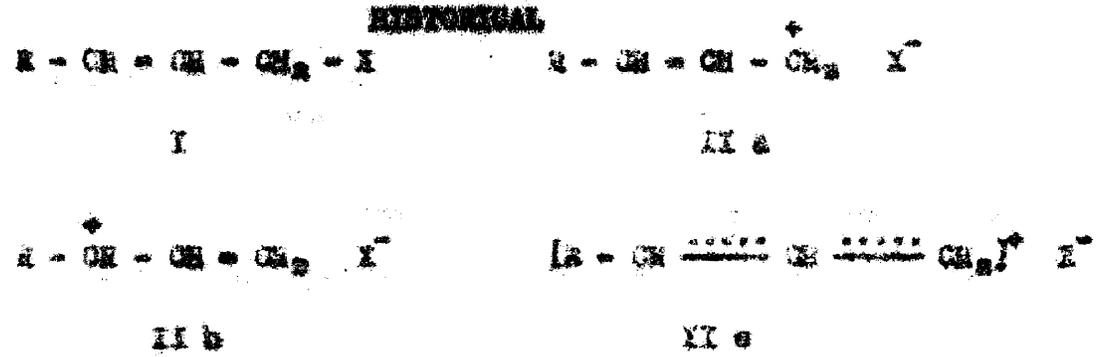

Although this thesis is composed of two parts, both are concerned with cyclopropylcarbinyl systems. Each part will be treated separately for the purpose of clarity. The parts are:

PART I: The Synthesis and Solvolysis of Trifluoroacetates of Certain Cyclopropylcarbinols.

PART II: The Synthesis and Attempted Thermal Rearrangement of Cyclopropylcarbinyl Phenyl Ether.

INTRODUCTION

Allylic systems are unusually reactive in solvolytic displacement reactions, presumably because of delocalization of the pi electrons of the double bond in the transition state. Thus, a unimolecular displacement in an allylic system (I) may be facilitated by resonance contributions in the carbocationic reactivity from structures such as II a and II b, which may be summarized as II c.

Analogies have been drawn between the cyclopropane ring and the carbon-carbon double bond (1). On this basis, the cyclopropylcarbinyl system, being comparable with the allylic system, would also be expected to be very reactive in solvolytic displacement reactions, and this is indeed the case. Thus, the rate of solvolysis of cyclopropylcarbinyl chloride (III a) in aqueous ethanol was 20 times faster than p-ethylallyl chloride (IV) and cyclopropylcarbinyl bromide (III b) solvolyzed 26 times faster than allyl bromide (V a) (2).

HISTORICAL

Allylic systems are unusually reactive in solvolytic displacement reactions, presumably because of delocalization of the pi electrons of the double bond in the transition state. Thus, a unimolecular displacement in an allylic system (I) may be facilitated by resonance contributions in the cationic moiety from structures such as II a and II b, which may be summarized as II c.

I

II a

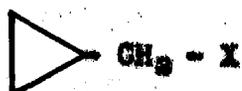

II b

II c

Analogies have been drawn between the cyclopropane ring and the carbon-carbon double bond (1). On this basis, the cyclopropylcarbinyl system, being comparable with the allylic system, would also be expected to be very reactive in solvolytic displacement reactions, and this is indeed the case. Thus, the rate of solvolysis of cyclopropylcarbinyl chloride (III a) in aqueous ethanol was 40 times faster than β -methylallyl chloride (IV) and cyclopropylcarbinyl bromide (III b) solvolyzed 26 times faster than allyl bromide (V a) (2).

III a, X = Cl

III b, X = Br

III c, X = O-SO₂-

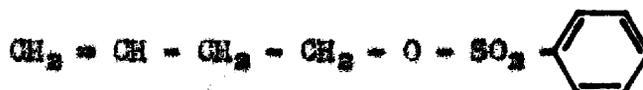

IV

V a, X = Br

V b, X = O-SO₂-

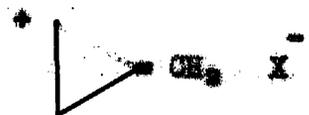

VI a

Also, the ethanolysis of cyclopropylcarbonyl benzenesulfonate (III c) was 14 times faster than allyl benzenesulfonate (V b) and 1000 times faster than allylcarbonyl benzenesulfonate (VI a) (3).

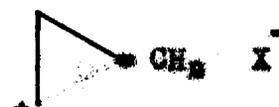

This exceptional reactivity of cyclopropylcarbonyl systems in unimolecular displacement reactions has been attributed to contributing resonance structures such as VII a, VII b and VII c which may be summarized as VII d and VII e (2,3).

VII a

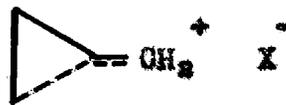

VII b

VII c

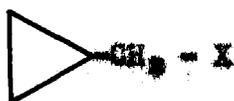

VII d

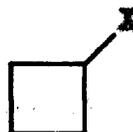

VII e

The products also indicate participation of the cyclopropane ring. In the hydrolysis of cyclopropylcarbonyl chloride and cyclobutyl chloride (VIII a), and in the diazotisation of cyclopropylcarbonylamine (III d) and cyclobutylamine (VIII b), the same ratio of products was obtained; 48% cyclopropylcarbinol (III e), 47% cyclobutanol (VIII c) and 5% allylcarbinol (VI b) (2).

III d, X = NH₂

III e, X = OH

VIII a, X = Cl

VIII b, X = NH₂

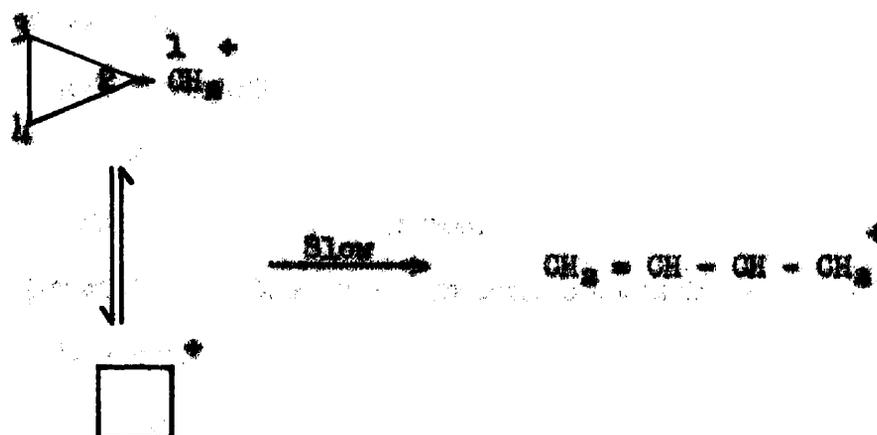

VIII c, X = OH

VIII d, X = OSO₂--CH₃

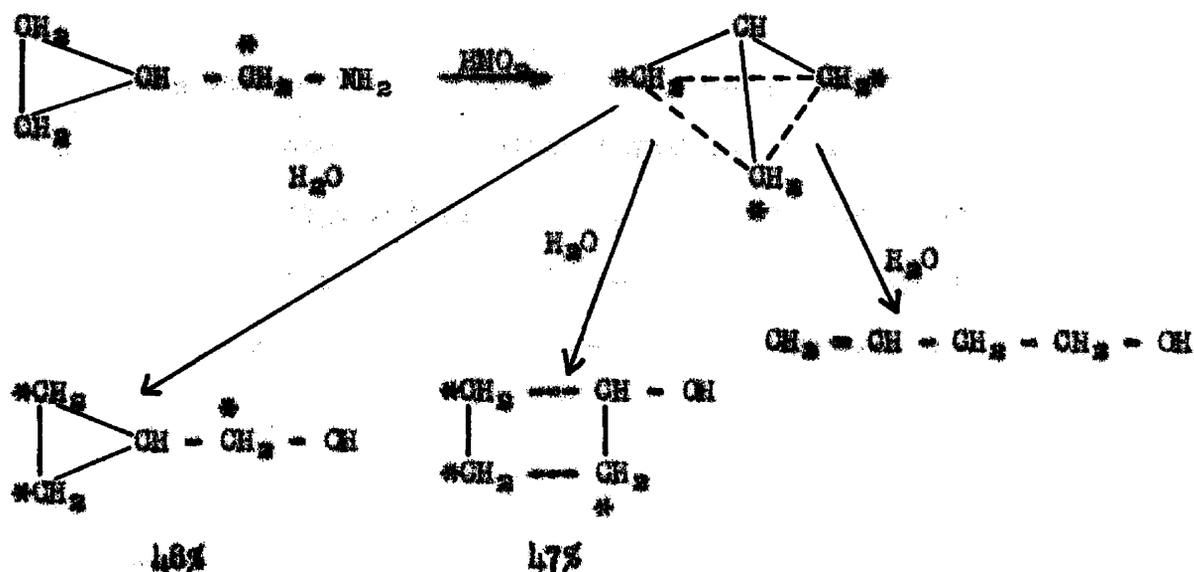

VI b

In addition, the acetylation of cyclopropylcarbonyl chloride (2) and of cyclobutyl p-toluenesulfonate (VIII d) (4) gave the same ratio of products (but different from that just mentioned); cyclopropylcarbonyl and cyclobutyl acetates were formed in a ratio of 2.8 to 1. These results were explained (2) in terms of rapid interconversion of cyclopropylcarbonyl and cyclobutyl cations with a slow and essentially irreversible reaction to allylcarbonyl derivatives.

As a result of such interconversions each of the original carbon atoms 1, 3 and 4 may appear in the side-chain of the cyclopropylcarbinyl compound in the product.

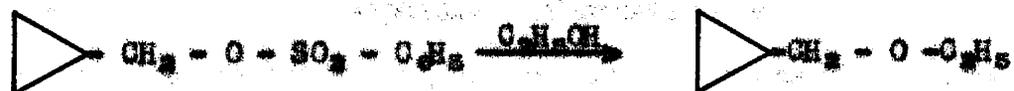

A similar explanation was suggested by Roberts and Masur (5) to account for the results obtained when cyclopropylcarbinylamine-1-C¹⁴ was treated with nitrous acid. In a "non-classical"

carbocation ion of the type shown in the scheme, which has a three-fold axis of symmetry so that the two methylene groups of the cyclopropane

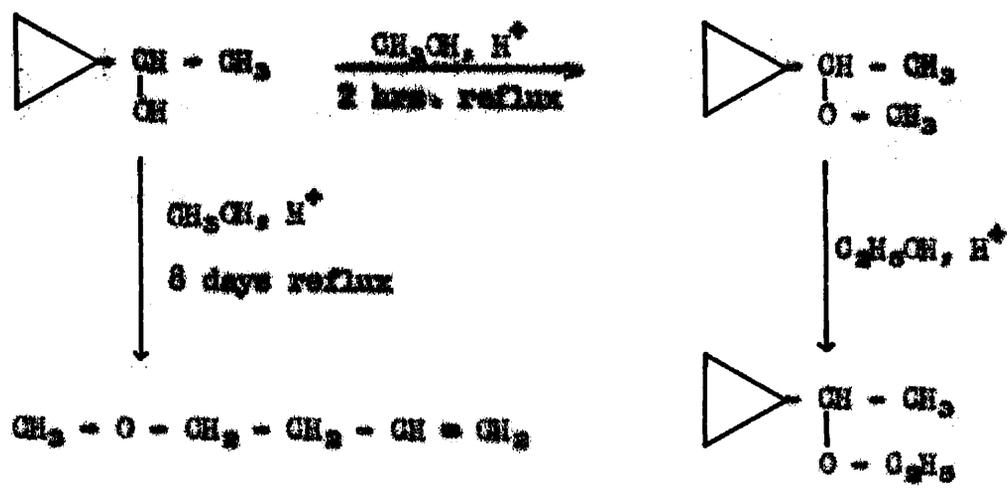

ring become equivalent with the exocyclic methylene group, the C^{14} should be equally distributed among the starred carbon atoms in each product. This was the case with the cyclobutanol. However, in the cyclopropylcarbinol formed, an excess of C^{14} (45% rather than 33.3%) over that predicted by the non-classical intermediate was found at the carbinol carbon atom, and only 54% (rather than 66.7%) was found in the ring. This was explained by suggesting that more than one mechanism may be operative.

In three instances no rearrangement or ring opening occurred during solvolysis. Cyclopropylcarbinyl benzenesulfonate in absolute ethanol was found to give only cyclopropylcarbinyl ethyl ether in a first order process (3).³

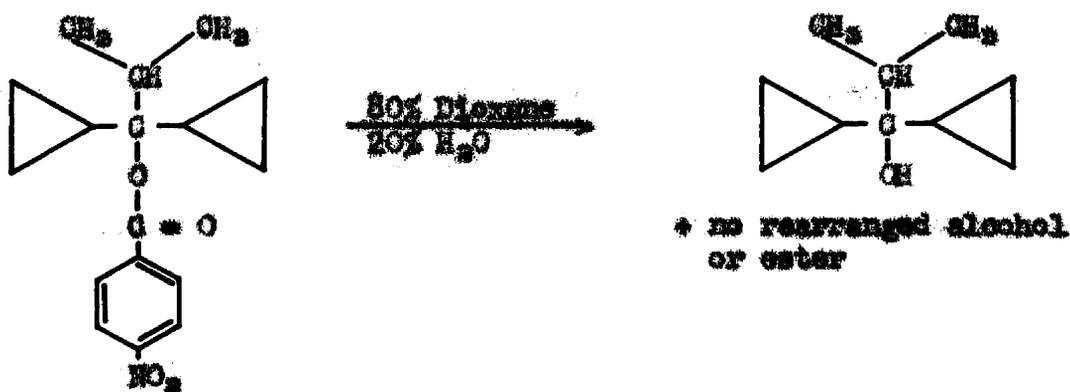

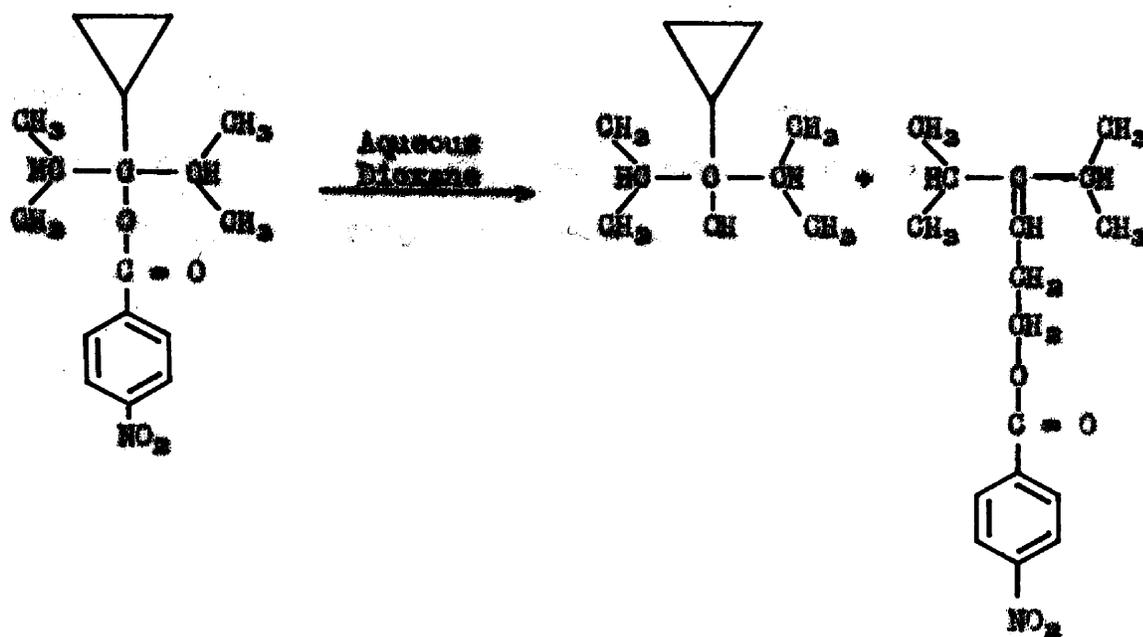

The second instance is the reaction of cyclopropylmethylcarbinol in methanol, in the presence of p-toluenesulfonic acid, to give only cyclopropylmethylcarbinyl methyl ether (11). Also, the methyl ether, under similar conditions, gave only the ethyl ether. Only after eight days at reflux was any allylcarbinyl methyl ether formed.

³It should be noted, however, that cyclopropylcarbinyl benzenesulfonate in chloroform was reported to rearrange rapidly to allylcarbinyl benzenesulfonate and a small amount of the cyclobutyl isomer.

Finally, Hart and Sadrri (12) have recently reported the solvolysis of several *p*-nitrobenzoates of tertiary alcohols and one secondary alcohol containing the cyclopropylcarbonyl group. The rates of solvolysis of these esters in aqueous dioxane followed first order kinetics, and were the fastest recorded for aliphatic *p*-nitrobenzoates. No rearranged alcohols were observed in the solvolysis products. In some instances, however, solvolysis to alcohol and *p*-nitrobenzoic acid was incomplete. In these cases, another product, an allylcarbonyl ester, was formed, but these esters were not solvolyzed under the reaction conditions.

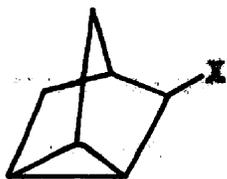

| | | |
|------------------------------------|-----|-----|
| 70% Dioxane - 30% H ₂ O | 96% | 45 |
| 90% Dioxane - 10% H ₂ O | 88% | 72% |

One cyclopropyl group on the carbonyl carbon atom was superior to an isopropyl or *t*-butyl group in facilitating solvolysis. A second cyclopropyl group caused a rate increase nearly equal to that of the first. The results were interpreted in terms of a mechanism involving ionization to ion-pairs, from which rearranged ester could be formed via internal return. The solvolysis products could be formed from either the ion-pair or from dissociated ions. This interpretation is similar to that of Kosover and Winstein (13) in the methanolyses of 3,5-cyclocholestan-6-yl trichloroacetate.

The inclusion of the three membered ring in a cage structure may limit its ability to participate in the solvolysis reaction. For example, the solvolysis of 3-chloronortricyclene (IXa), a cyclopropyl-carbonyl derivative with rather special geometric limitations, in

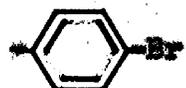

aqueous ethanol is reported to be 50 to 100 times slower than cyclopropylcarbinyl chloride, and approximately the same as cyclopentyl chloride (6,7). A suggested reason for

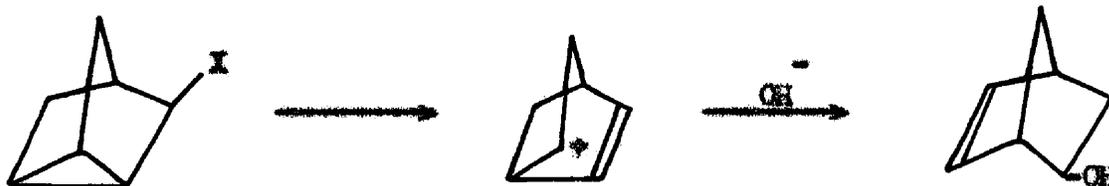

IX a, X = Cl

IX b, X = Br

IX c, X = OH

IX d, X = O - SO₂ -  - Br

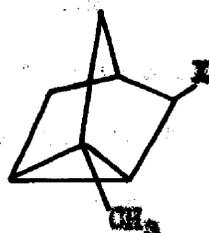

the low reactivity of the 3-halomtricycloene was steric inhibition of resonance. The only product reported in the solvolysis of the chloride (IX a) or the bromide (IX b) was 3-hydroxymtricycloene (IX c) (8). By analogy with other cyclopropylcarbinyl systems, rearrangement according to the following scheme could have accompanied solvolysis if participation by the cyclopropane ring had occurred.

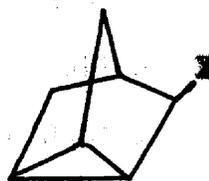

Winstein (9), however, observed that the acetolysis of the p-bromobenzene sulfonate (IX d) was about 200 times faster than that of cyclohexyl p-bromobenzene sulfonate and concluded that the system had

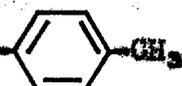

considerable reactivity. It should be noted that the conclusions concerning the reactivity of the β -nortricyclyl derivatives depended on whether they were compared with cyclopentyl or with cyclohexyl systems.

In another study (10), two 1-methyl- β -nortricyclyl derivatives (I a, I b) were found to solvolyse up to 200 times more rapidly than did the corresponding methyl-free β -nortricyclyl derivatives (II a, II c).

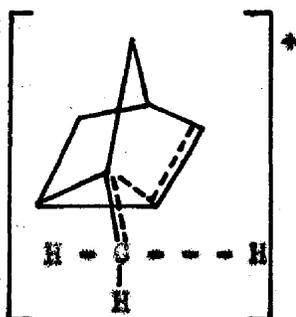

I a, X = Cl

II c, X = O-SO₂--CH₃

The rate enhancing effect of the methyl group was attributed to assistance of homoallylic participation, which might be pictured as follows:

There are some aspects of the previous work on primary and secondary cyclopropylcarbonyl systems, that are not entirely satisfactory. Because of purification difficulties, the kinetic work on cyclopropylcarbonyl chloride, bromide and benzenesulfonate was not done on pure (less than

90% pure) compounds. Also, in the conversion of cyclopropylmethylcarbinol to cyclopropylmethylcarbinyl methyl ether in methanol, in the presence of *p*-toluenesulfonic acid, it was not established that the reaction was kinetically first order. One purpose of the present investigation was to prepare pure, stable cyclopropylcarbinyl derivatives whose solvolyses could be studied.

Also, the only studies on cyclopropylcarbinyl analogs in nortricyclene compounds have been on *β*-substituted derivatives, where participation of the three-membered ring may be limited for geometric reasons. It was therefore decided to study the solvolyses of *l*-substituted nortricyclene derivatives in which this geometric limitation was not present.

In an attempt to find an ester suitable for solvolysis studies the *p*-nitrobenzoate, the 2,4-dinitrobenzoate and the mono-, di-, and trichloroacetates of cyclopropylcarbinol were prepared. These compounds were found to be stable and could be readily purified, but their solvolysis was too slow for convenient study. Finally, the trifluoroacetate of cyclopropylcarbinol was prepared and found to be satisfactory for kinetic studies.

The solvolysis of the trifluoroacetates of several primary, secondary and tertiary alcohols has recently been reported (14,15,16). The esters of the primary and secondary alcohols were reported to solvolyse by acyl-oxygen cleavage, while the esters of the tertiary alcohols solvolyse by alkyl-oxygen cleavage. Because of the solvolytic

reactivity of cyclopropylcarbonyl systems it was anticipated that the trifluoroacetates of the cyclopropylcarbinols would solvolyze by alkyl-oxygen cleavage.

EXPERIMENTAL

EXPERIMENTAL¹

A. Synthesis

Cyclopropylcarbinol

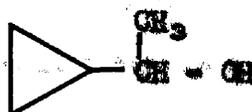

In a dry, 5-l. three-necked flask equipped with a Hershberg stirrer, a dropping funnel and a reflux condenser was placed 800 ml. of anhydrous ether and 80.0 g. (2.1 moles) of lithium aluminum hydride. After the mixture was stirred for one hour it was cooled in an ice bath and a solution of 160 g. (1.86 moles) of cyclopropanecarboxylic acid (40) in 300 ml. of anhydrous ether was added dropwise (one and one-half hours) with stirring. The mixture was stirred for an additional hour at room temperature, then was cooled (ice bath) and the excess lithium aluminum hydride decomposed (17) cautiously with successive portions of 80 ml. of water, 80 ml. of 15% sodium hydroxide and 240 ml. of water. The solution was stirred one hour at room temperature, filtered, and the aluminum salts washed two times with 100-ml. portions of ether. The ether solution was dried over Drierite, filtered, and the solvent removed. Distillation of the residue through a thirteen-inch Fenske column yielded 113 g. (85%) of cyclopropylcarbinol, b.p. 123.5-124.0°, n_D^{20} 1.4301.

¹Analyses in this thesis were performed by Spang Microanalytical Laboratory, Ann Arbor, Michigan.

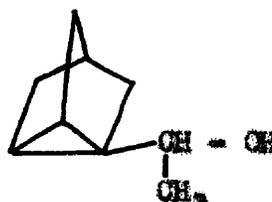

The alcohol gave a single peak (Anal., 14 min.) in the vapor chromatograph.¹

Cyclopropylmethylecarbinol

Cyclopropyl methyl ketone (supplied by the Aldrich Chemical Co., Milwaukee, Wisconsin) was reduced to cyclopropylmethylecarbinol using a procedure analogous to that for cyclopropylcarbinol. The yield of alcohol was 87%, b.p. 122.0-122.5°, n_D^{20} 1.4311. The alcohol gave a single peak (Anal., 13 min.) in the vapor chromatograph.

Northricyl- and methylnorthricylcarbinol

These alcohols were prepared by Robert A. Martin (48). The physical constants for northricylcarbinol were b.p. 52-54° at 0.8 mm.,

¹A Perkin-Elmer Model 154 Vapor Fractionator was used for analysis or purification of products, with three different columns: a two-meter one-fourth inch analytical column (abbreviated, Anal.) containing Perkin-Elmer packing type "A" (didecyl phthalate on firebrick), a three-meter one-inch preparative column with the same packing (abbreviated, Prep. A), and a similar preparative column with packing of type "O" (silicone; abbreviated, Prep. O). The usual operating conditions, unless otherwise specified, were a temperature of 94 ± 1° and a pressure of 10 p.s.i. of oil pumped nitrogen through the column. The type of column and the time of appearance, in minutes, of the maximum conductance are listed.

n_D^{25} 1.4912. The physical constants for methyltricyclopentylcarbinol were b.p. 63-64° at 1.0 mm., n_D^{25} 1.4837.

Trifluoroacetyl chloride

Trifluoroacetic acid (34.5 g., 0.3 mole) and benzoyl chloride (84 g., 0.6 mole) were mixed in a 200-ml. round-bottomed flask, and the flask immediately connected to a twelve-inch Vigreux column. The top of the column was attached to a 100-ml. round-bottomed flask, filled with 90 ml. of anhydrous ether, so that any gas produced would have to bubble through the ether. A dry ice-isopropyl alcohol bath was used to cool the ether. The reaction flask was heated gently (maximum of 35°) and the trifluoroacetyl chloride collected in the cooled ether. After heating for four hours the ether solution was removed and stoppered, and allowed to warm almost to room temperature.

Cyclopropylcarbinyl trifluoroacetate

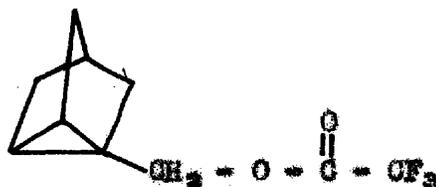

A 300-ml. three-necked flask fitted with a Hershberg stirrer, a reflux condenser and a dropping funnel was charged with 50 ml. of anhydrous ether and 2.40 g. (0.1 mole) of sodium hydride. A solution of 7.20 g. (0.1 mole) of cyclopropylcarbinol in 50 ml. of anhydrous ether was added dropwise in thirty minutes. After addition was complete the mixture was refluxed and stirred for five or six hours.

The suspension of the sodium salt of the alcohol was cooled in an ice bath and a solution of trifluoroacetyl chloride in ether, prepared as previously described, added over a period of fifteen minutes. After the mixture was stirred for fifteen minutes it was filtered and then extracted three times with 25-ml. portions of ice-cold 10% sodium bicarbonate and once with ice-cold water. After drying over Drierite and removing the solvent, the residue was distilled through a Claisen head and the fraction boiling from 105-109° was collected. Fractionation through a semi-micro Vigreux column gave 13.4 g. (80%) of cyclopropylcarbinyl trifluoroacetate, b.p. 106.5-107.5°, n_D^{25} 1.3515. The ester gave a single peak (Anal., 9 min.) in the vapor chromatograph. The infrared spectrum of the ester is given in Figure 1.

Anal. Calc'd for $C_6H_7F_3O_2$: C, 42.87; H, 4.20

Found: C, 43.27, 43.31; H, 4.51, 4.47

Nortricyclylcarbinyl trifluoroacetate

This ester was prepared from 5.00 g. (0.04 mole) of nortricyclylcarbinol in a manner similar to that for cyclopropylcarbinyl trifluoroacetate. Distillation gave 7.44 g. (85%) of nortricyclylcarbinyl trifluoroacetate, b.p. 64.5-65.1° at 12 mm., n_D^{25} 1.4110-1.4114.

Anal. Calc'd for $C_{10}H_{11}F_3O_2$: C, 54.54; H, 5.04

Found: C, 54.63; H, 5.15

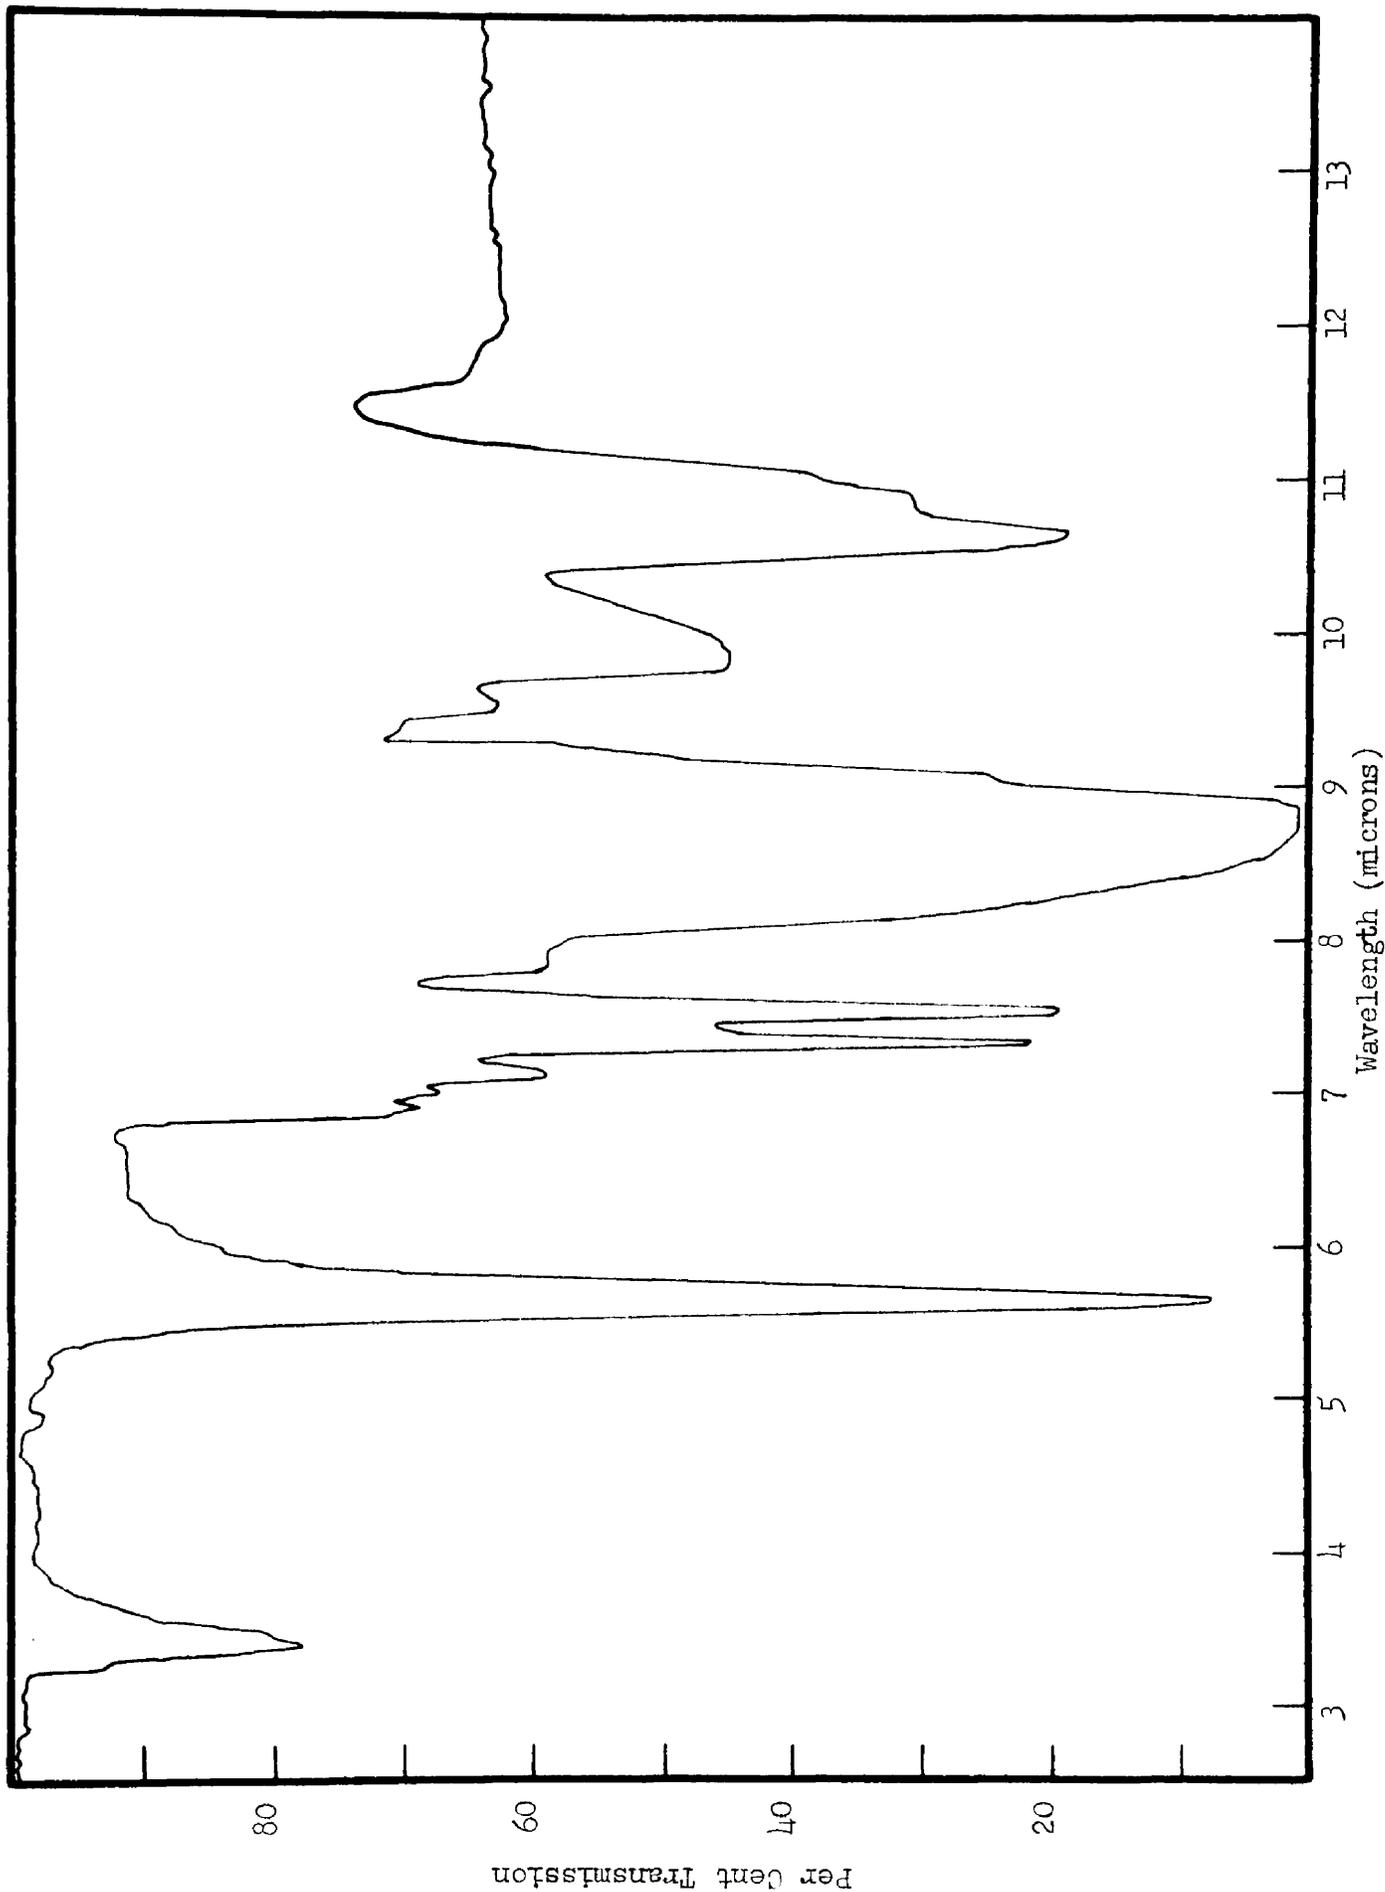

Figure 1. Infrared Spectrum of Cyclopropylcarbonyl Trifluoroacetate (CCl₄ solution).

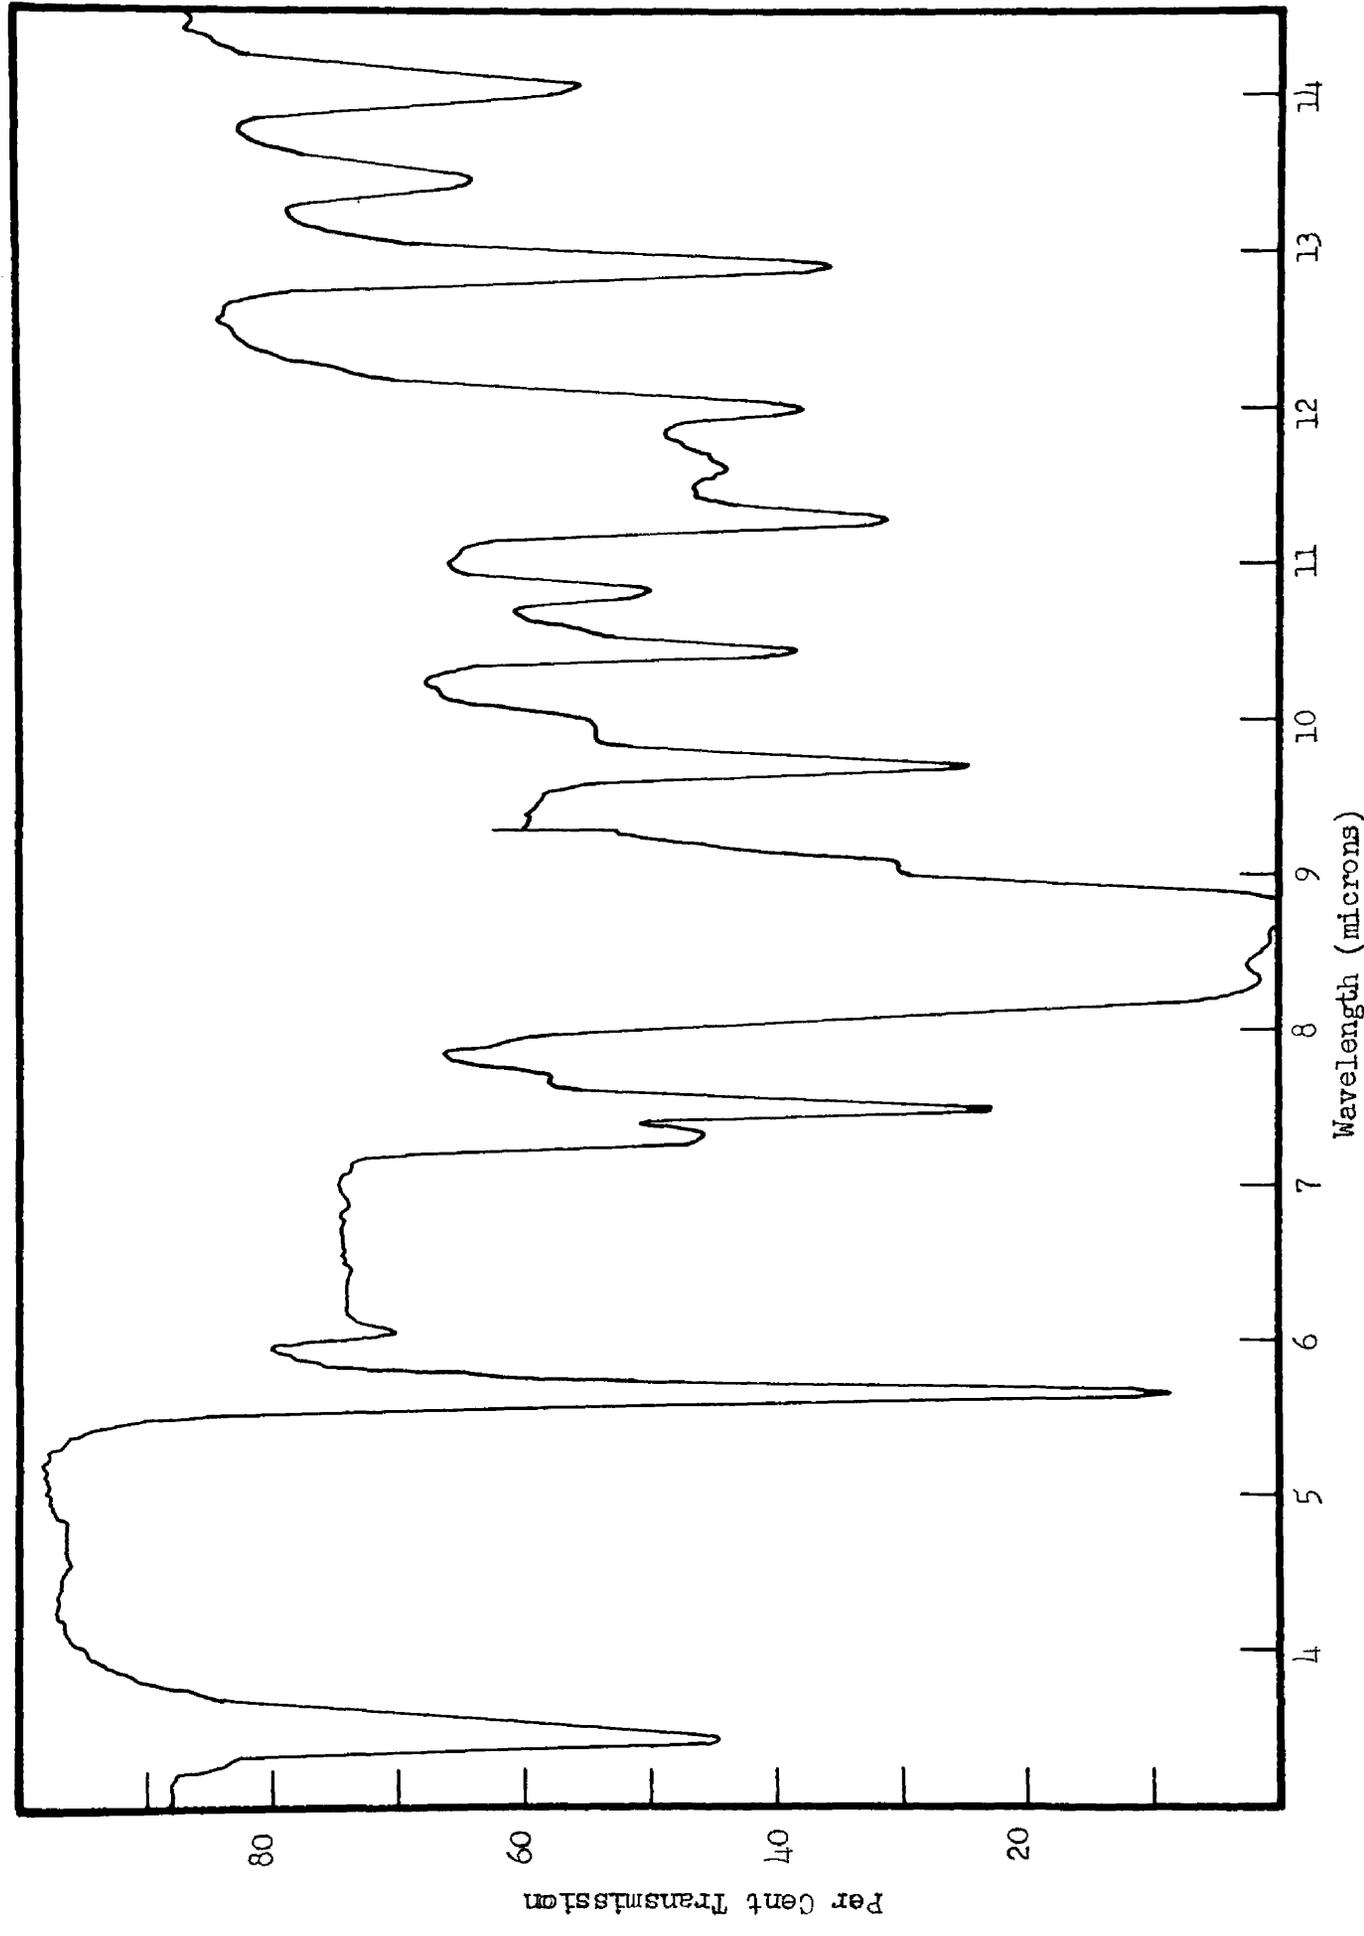

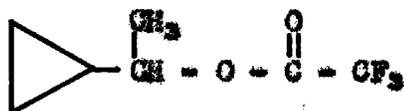

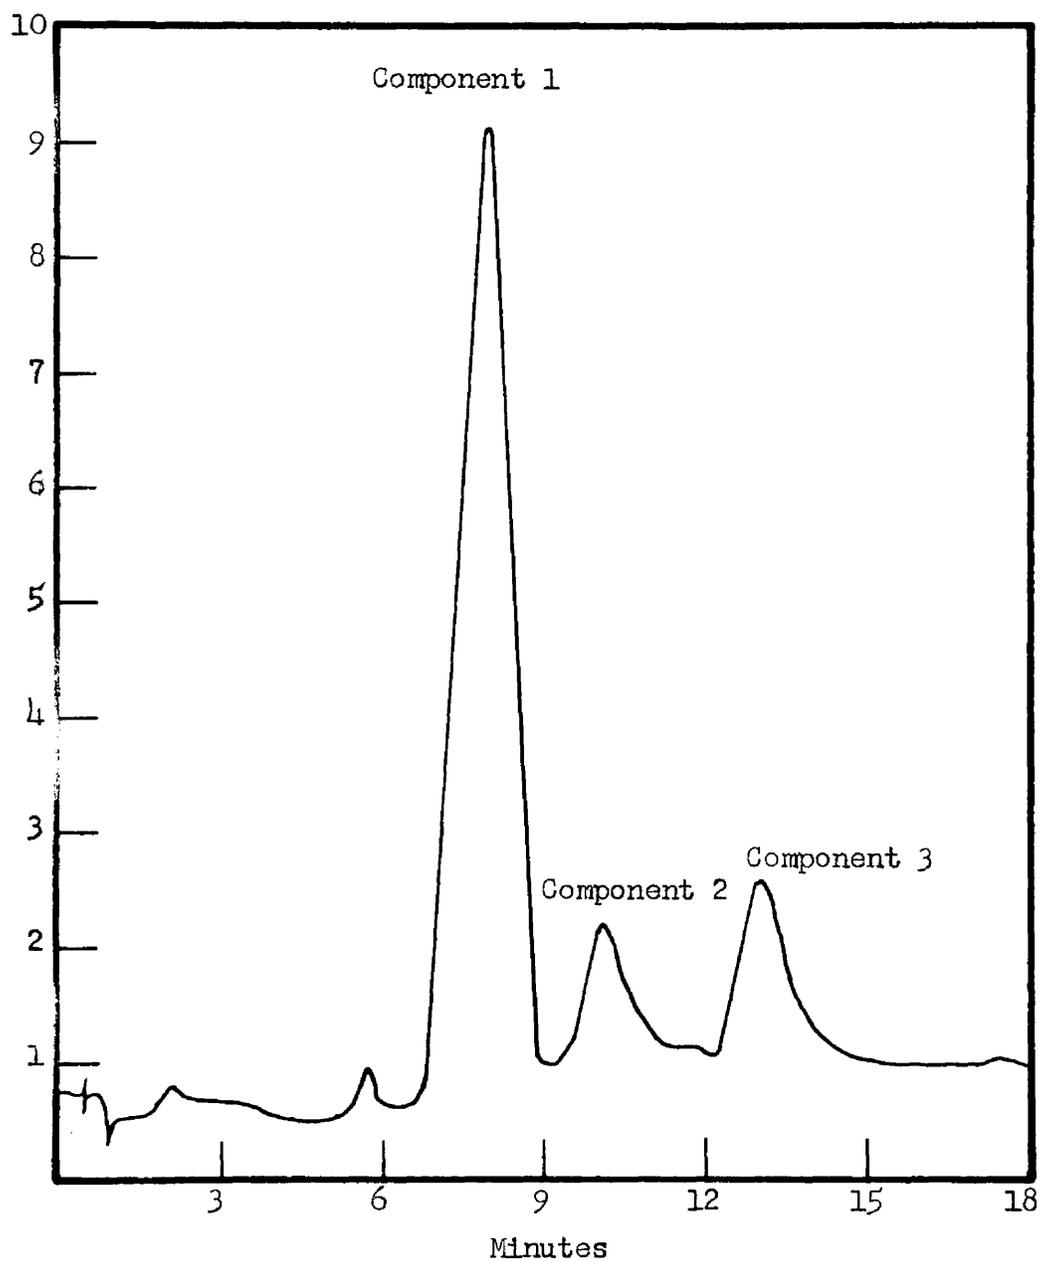

Figure 2. Infrared Spectrum of Nortricyclylcarbonyl Trifluoroacetate (CS₂ solution).

Cyclopropylmethylcarbonyl trifluoroacetate

A suspension of sodium cyclopropylmethylcarbinylate was prepared, as previously described, from 8.60 g. (0.1 mole) of cyclopropylmethylcarbinol (that gave a single peak in the vapor chromatograph) and 2.40 g. (0.1 mole) of sodium hydride in 100 ml. of anhydrous ether. A solution of trifluoroacetyl chloride, prepared as previously described, was added in ten minutes to the alcoholate solution cooled in an ice bath. The solution was stirred two hours at room temperature, filtered, washed three times with 25-ml. portions of ice-cold sodium bicarbonate and once with ice-cold water, and dried over Drierite. After removing the solvent the residue was distilled through a Claisen head and the fraction boiling 55-65° at 80-95 mm. was collected. Fractionation through a semi-micro Vigreux column gave fractions with b.p. 58-60° at 80-90 mm. and n_D^{20} 1.3583-1.3601. The vapor chromatograph (Figure 3) had three main peaks (Anal., 8 min., 10 min. and 13 min.). These will be referred to as Components, 1, 2 and 3, respectively. In another preparation of cyclopropylmethylcarbonyl trifluoroacetate, using a larger excess of trifluoroacetyl chloride, vapor chromatography indicated that less of Component 1 and more of Component 2 was formed.

Attempts to separate Components 1, 2 and 3 by fractionation were unsuccessful. They could be separated by two passes through the vapor chromatograph (Prep. A, 31 min., 41 min. and 53 min.). Separate

Figure 3. Vapor Chromatograph of Reaction Product in the Preparation of Cyclopropylmethylcarbonyl Trifluoroacetate (Analytical Column).

distillation of these fractionator fractions gave the three components with an estimated purity of at least 98%, as indicated by vapor chromatography. Component 3 was shown to be cyclopropylmethylecarbinol by comparison of physical constants and infrared spectra, and by vapor chromatography.

Component 1 had b.p. 57-58° at 80 mm. and n_D^{25} 1.3576-1.3579. The infrared spectrum (Figure 4) indicated that it was an ester. There is an absorption band at 3.23 μ and there is also a band at 1.65 μ in the near infrared spectrum. These bands are consistent with the presence of a cyclopropane ring (18,21a).

The ester (0.50 g.) was hydrolyzed by shaking with 1 ml. of 6 N sodium hydroxide. The base solution was extracted with carbon tetrachloride and the extracts were dried over sodium sulfate. After filtering, an infrared spectrum was obtained that was identical with that of pure cyclopropylmethylecarbinol. A phenylurethane was obtained from the carbon tetrachloride solution, m.p. 69-70° (reported m.p. 69.6-70.5°) (19) after recrystallization from petroleum ether. Thus it appears that this ester is cyclopropylmethylecarbonyl trifluoroacetate.

Anal. Calc'd. for $C_7H_9F_3O_2$: C, 46.16; H, 4.98

Found: C, 46.51, 46.54; H, 5.23, 5.30

Component 2

The second component had b.p. 68-69° at 90 mm., n_D^{25} 1.3589-1.3592. The infrared spectrum (Figure 5) indicated that it was an ester.

Anal. Calc'd. for $C_7H_9F_3O_2$: C, 46.16; H, 4.98

Found: C, 45.94; H, 5.12

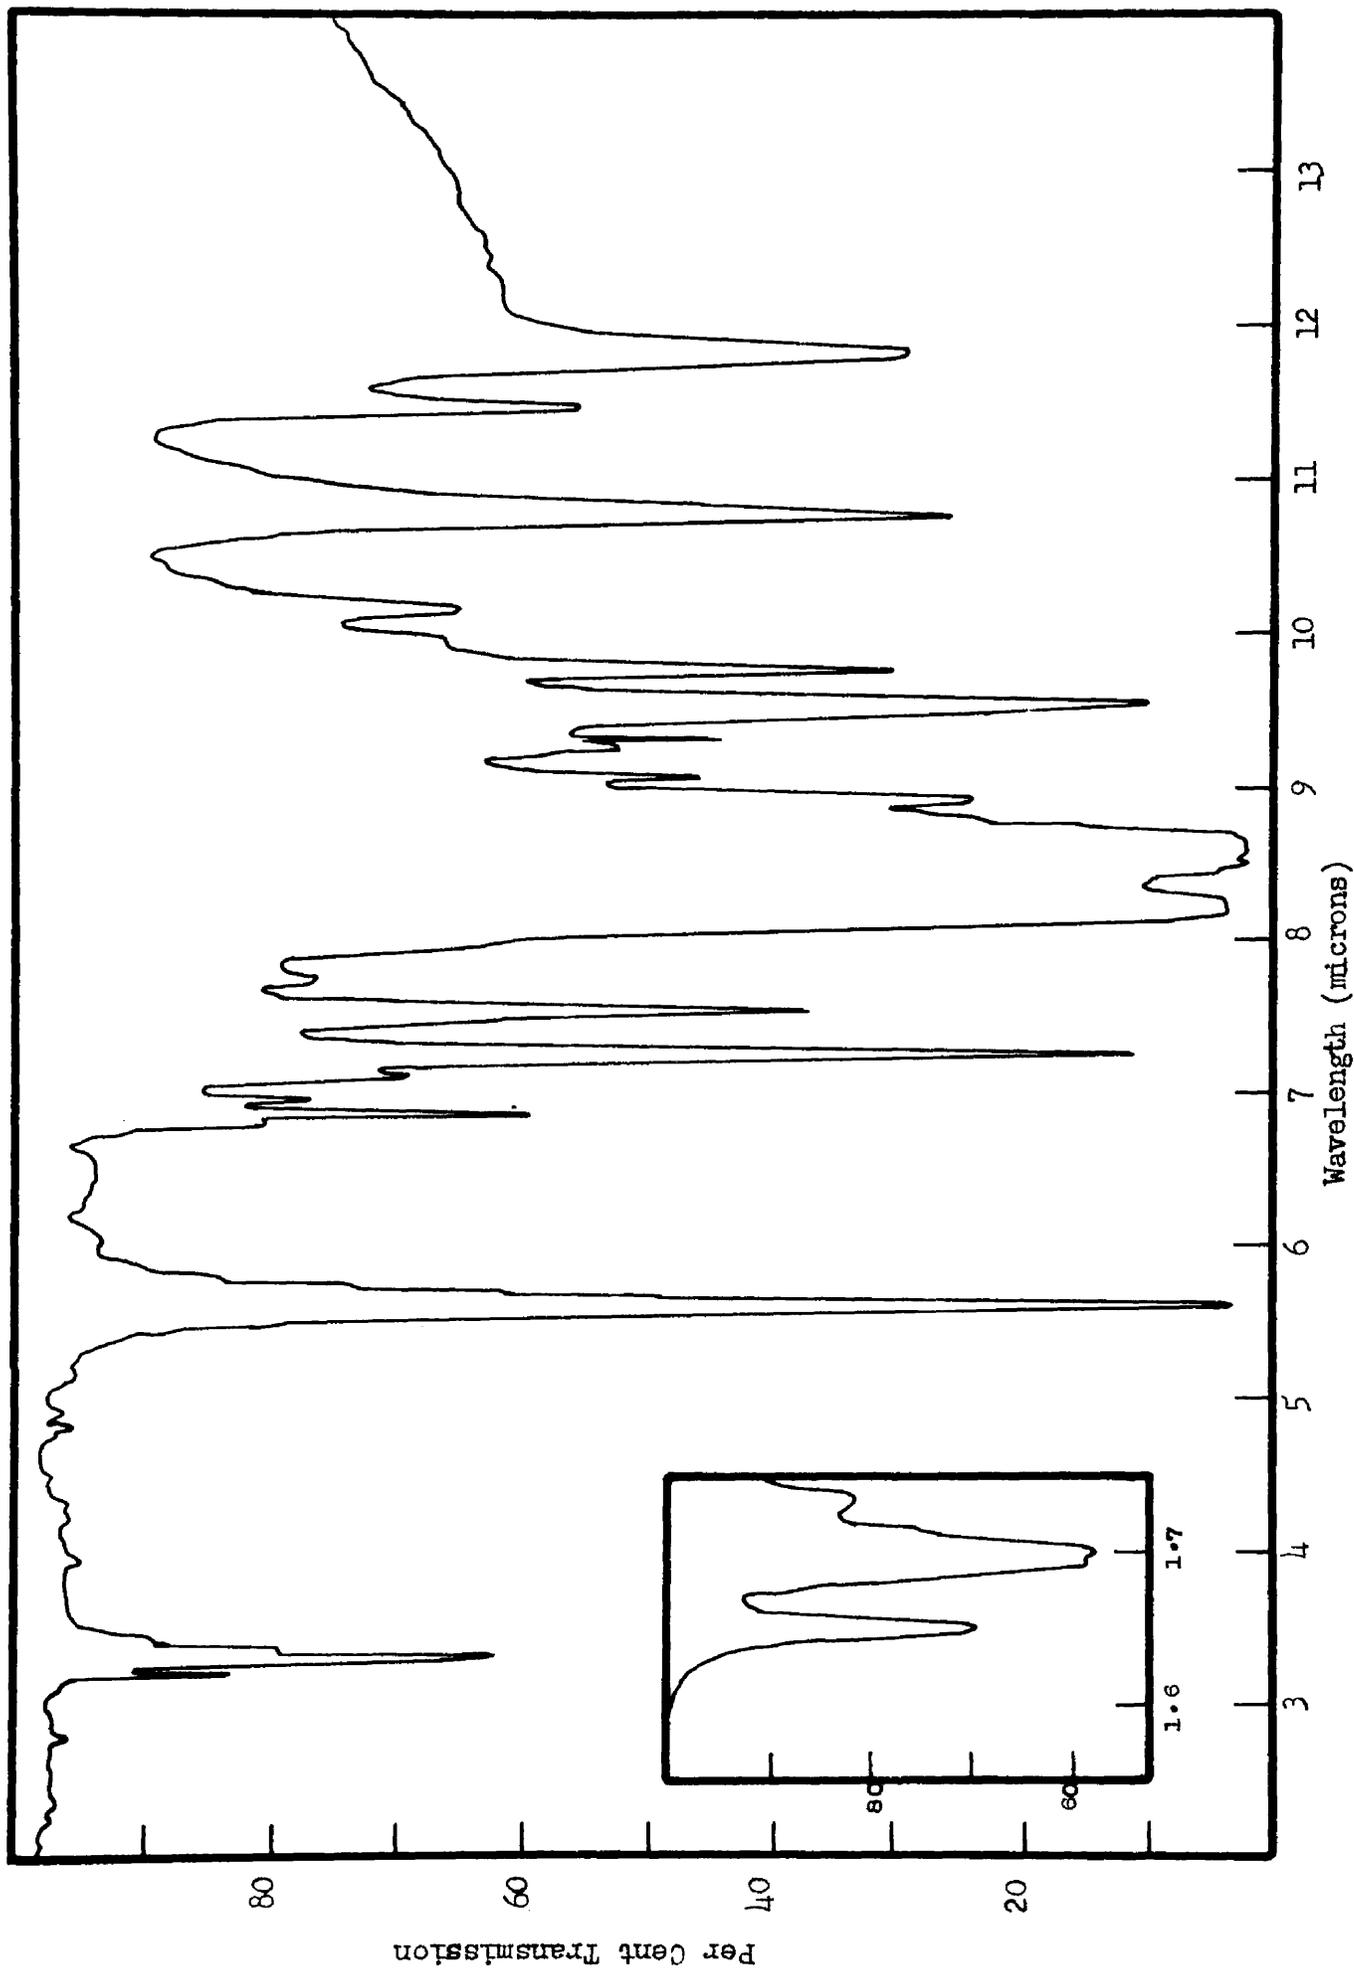

Figure 4. Infrared Spectrum of Cyclopropylmethylcarbonyl Trifluoroacetate (CCl_4 solution).

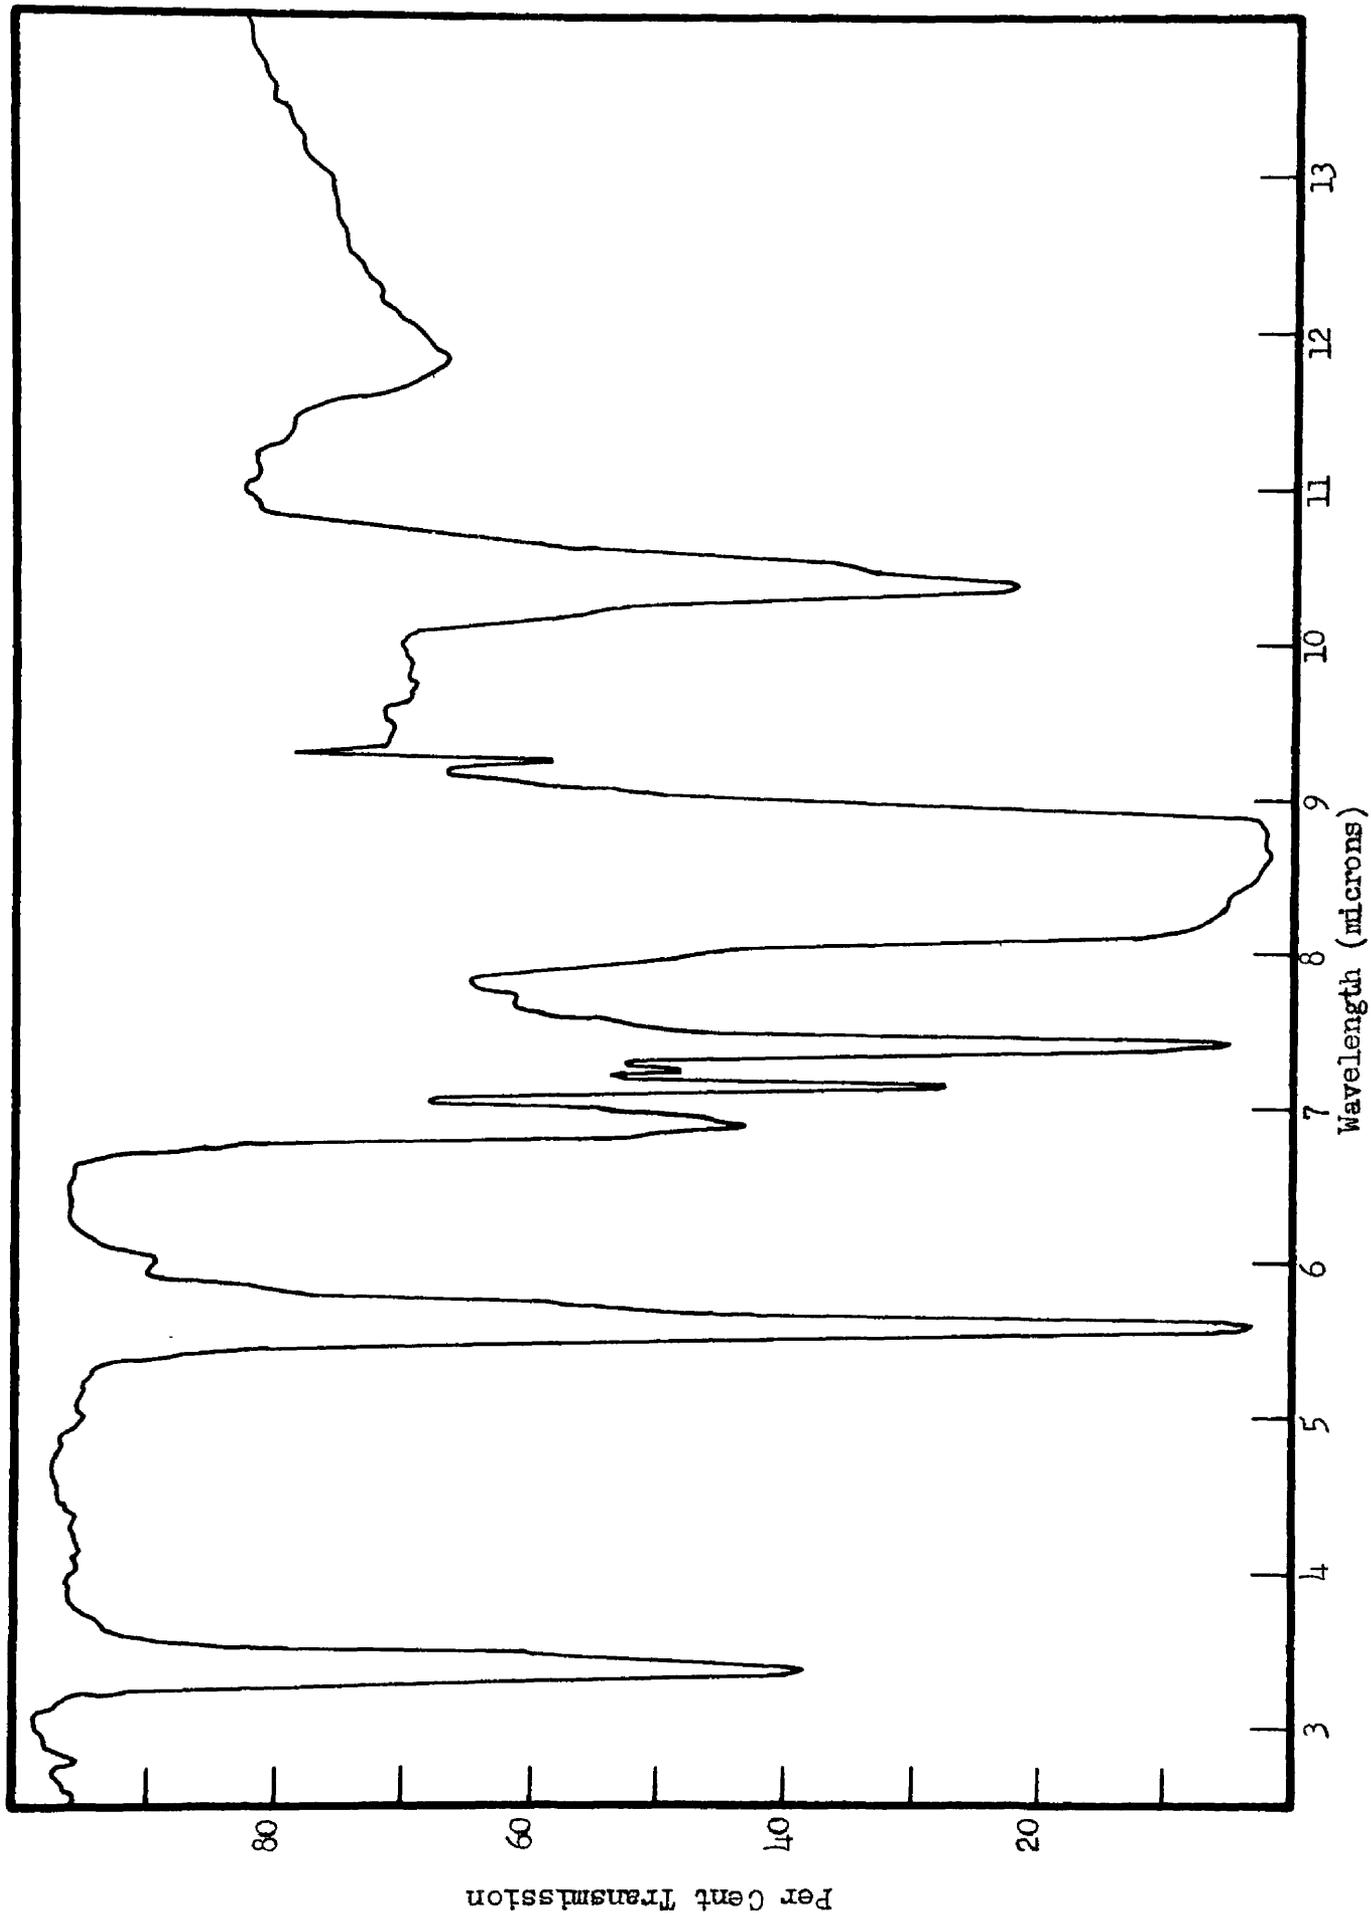

Figure 5. Infrared Spectrum of 2-Methylcyclobutyl Trifluoroacetate (CCl₄ solution).

There were no bands near 1.64μ in the near infrared spectrum or near 3.23μ in the infrared spectrum.

Base catalyzed hydrolysis of 0.26 g. of this ester by the same procedure as previously described gave an alcohol with an infrared spectrum (Figure 6) different from that of cyclopropylmethylcarbinol. The infrared spectrum of cyclopropylmethylcarbinol (Figure 7) is included for comparison. The carbon tetrachloride solution did not decolorize bromine in carbon tetrachloride. The phenylurethane of the alcohol, recrystallized from petroleum ether, melted at $39-41^{\circ}$.

Anal. Calc'd. for $C_{12}H_{18}NO_2$: C, 70.22; H, 7.37; N, 6.92

Found: C, 70.04; H, 7.37; N, 6.85.

Several recrystallizations from hexane, carbon tetrachloride, or methanol did not sharpen the melting point. An attempt was made to prepare the 3,5-dinitrobenzoate, but no product melting above room temperature could be obtained. The infrared spectra of the ester (Component 2) and of the alcohol both contained an absorption peak at about 10.4μ , which may be ascribed to the cyclobutane ring (21b).

The alcohol portion of this ester is probably 2-methylcyclobutanol. Data indicating the structure of this alcohol are discussed in the section on results. Nevertheless, Component 2 will be referred to as 2-methylcyclobutyl trifluoroacetate in the remainder of this thesis.

Reaction of Cyclopropylmethylcarbinol and Trifluoroacetic Acid

Cyclopropylmethylcarbinol (17.2 g., 0.20 mole) and trifluoroacetic acid (25.0 g., 0.22 mole) were mixed in a 50-ml. round-bottomed flask,

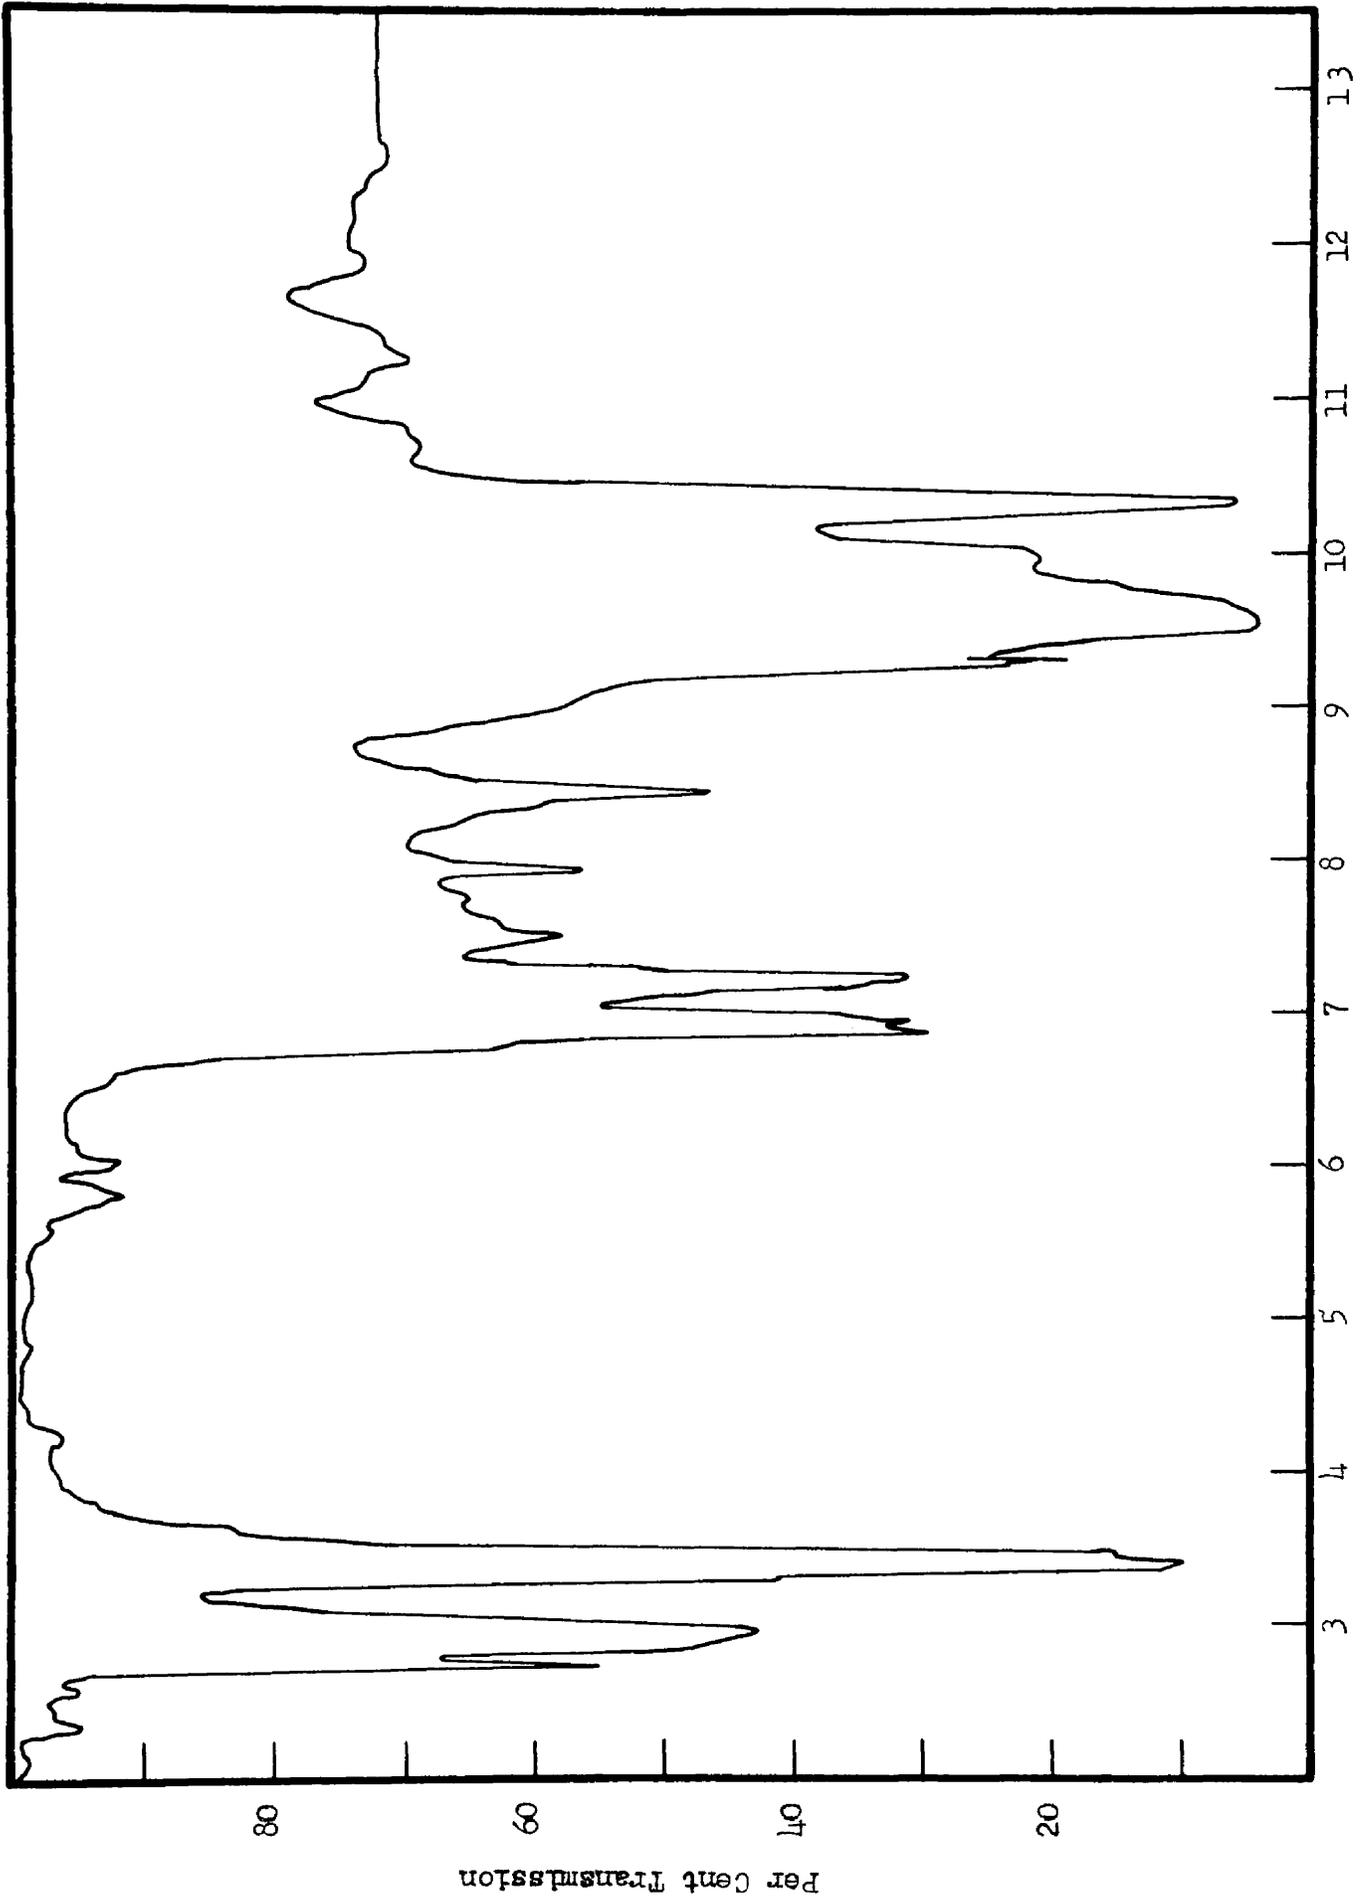

Figure 6. Infrared Spectrum of 2-Methylcyclobutanol (CCl_4 solution).

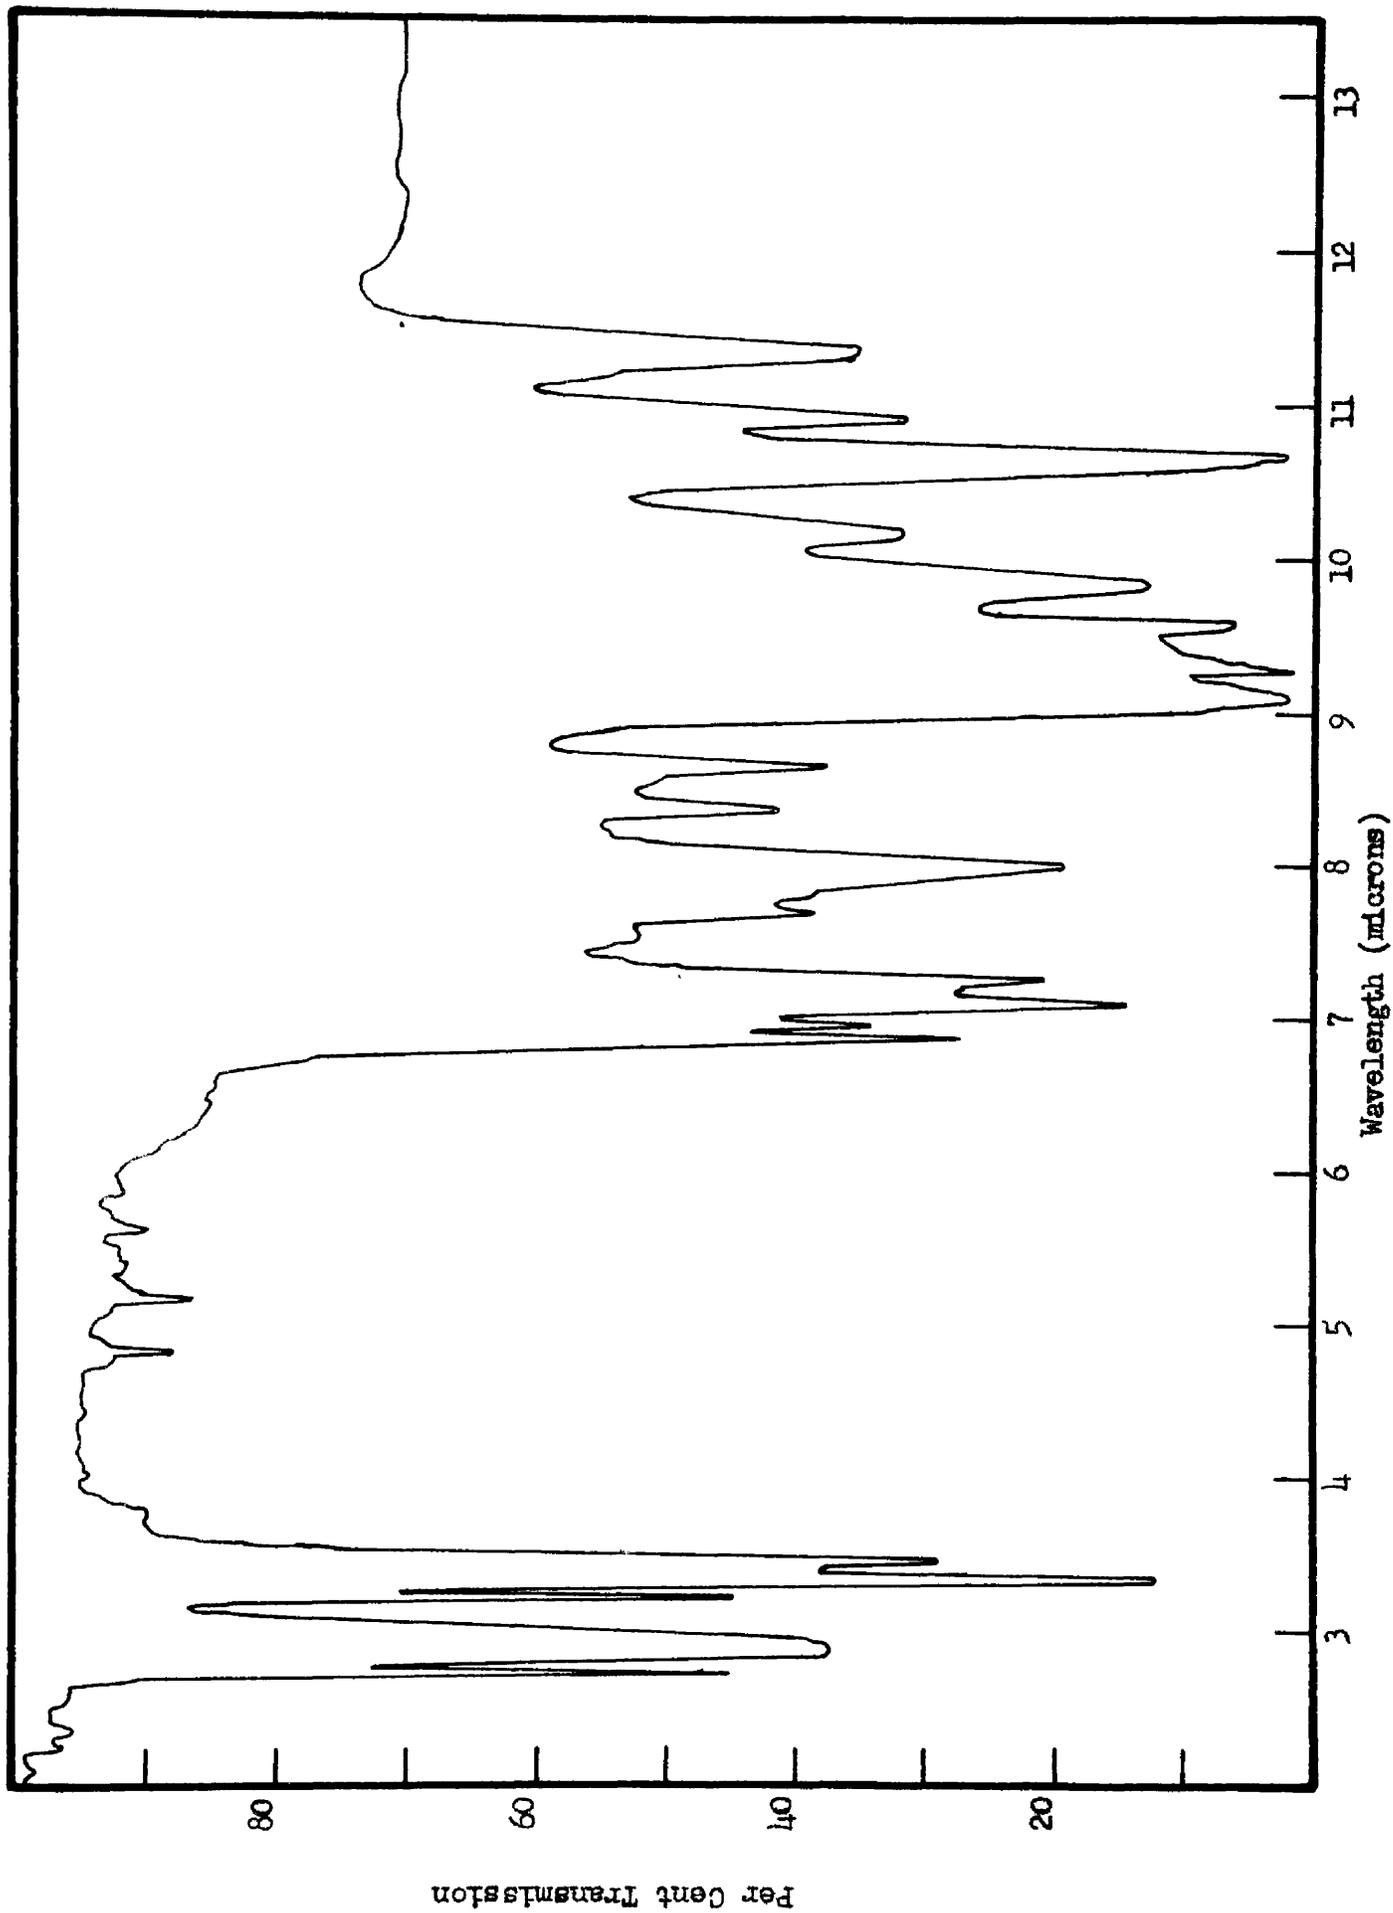

Figure 7. Infrared Spectrum of Cyclopropylmethylcarbinol (CCl_4 solution).

and the mixture became warm. After refluxing the solution for one-half hour it had become dark red, and refluxing was stopped. The solution was then allowed to remain at room temperature for 20 hours. After diluting with 50 ml. of ether the solution was extracted with ice-cold 10% sodium bicarbonate until the aqueous layer was neutral, and then it was washed once with water. The organic layer was dried over magnesium sulfate and distilled, b.p. 104-122°, n_D^{25} 1.3639-1.3649. Infrared analysis of this product indicated that it was primarily (about 90%) 2-methylcyclobutyl trifluoroacetate. The yield was about 40%.

Chromic acid oxidation of 2-Methylcyclobutanol (20)

In a 10-ml. Claisen flask, fitted with a 15-cm. piece of glass tubing (serving as condenser and addition tube) inserted to the bottom of the neck of the flask, was placed 0.50 g. of 2-methylcyclobutanol. The alcohol was heated almost to reflux. The oxidizing solution, prepared by dissolving 1.15 g. of sodium dichromate dihydrate in 1.5 ml. of water and slowly adding 1.0 ml. of concentrated sulfuric acid with swirling, was added dropwise through the glass tubing at such a rate that the oxidized material and water distilled slowly. After all of the oxidizing agent had been added (20 minutes) suction was applied to distill over as much of the organic components as possible. The water layer was saturated with potassium carbonate and the organic layer separated with a medicine dropper. The crude organic layer weighed 0.32 g. After drying over Drierite an infrared spectrum was obtained that had two peaks in the carbonyl region (Figure 8). This oxidation

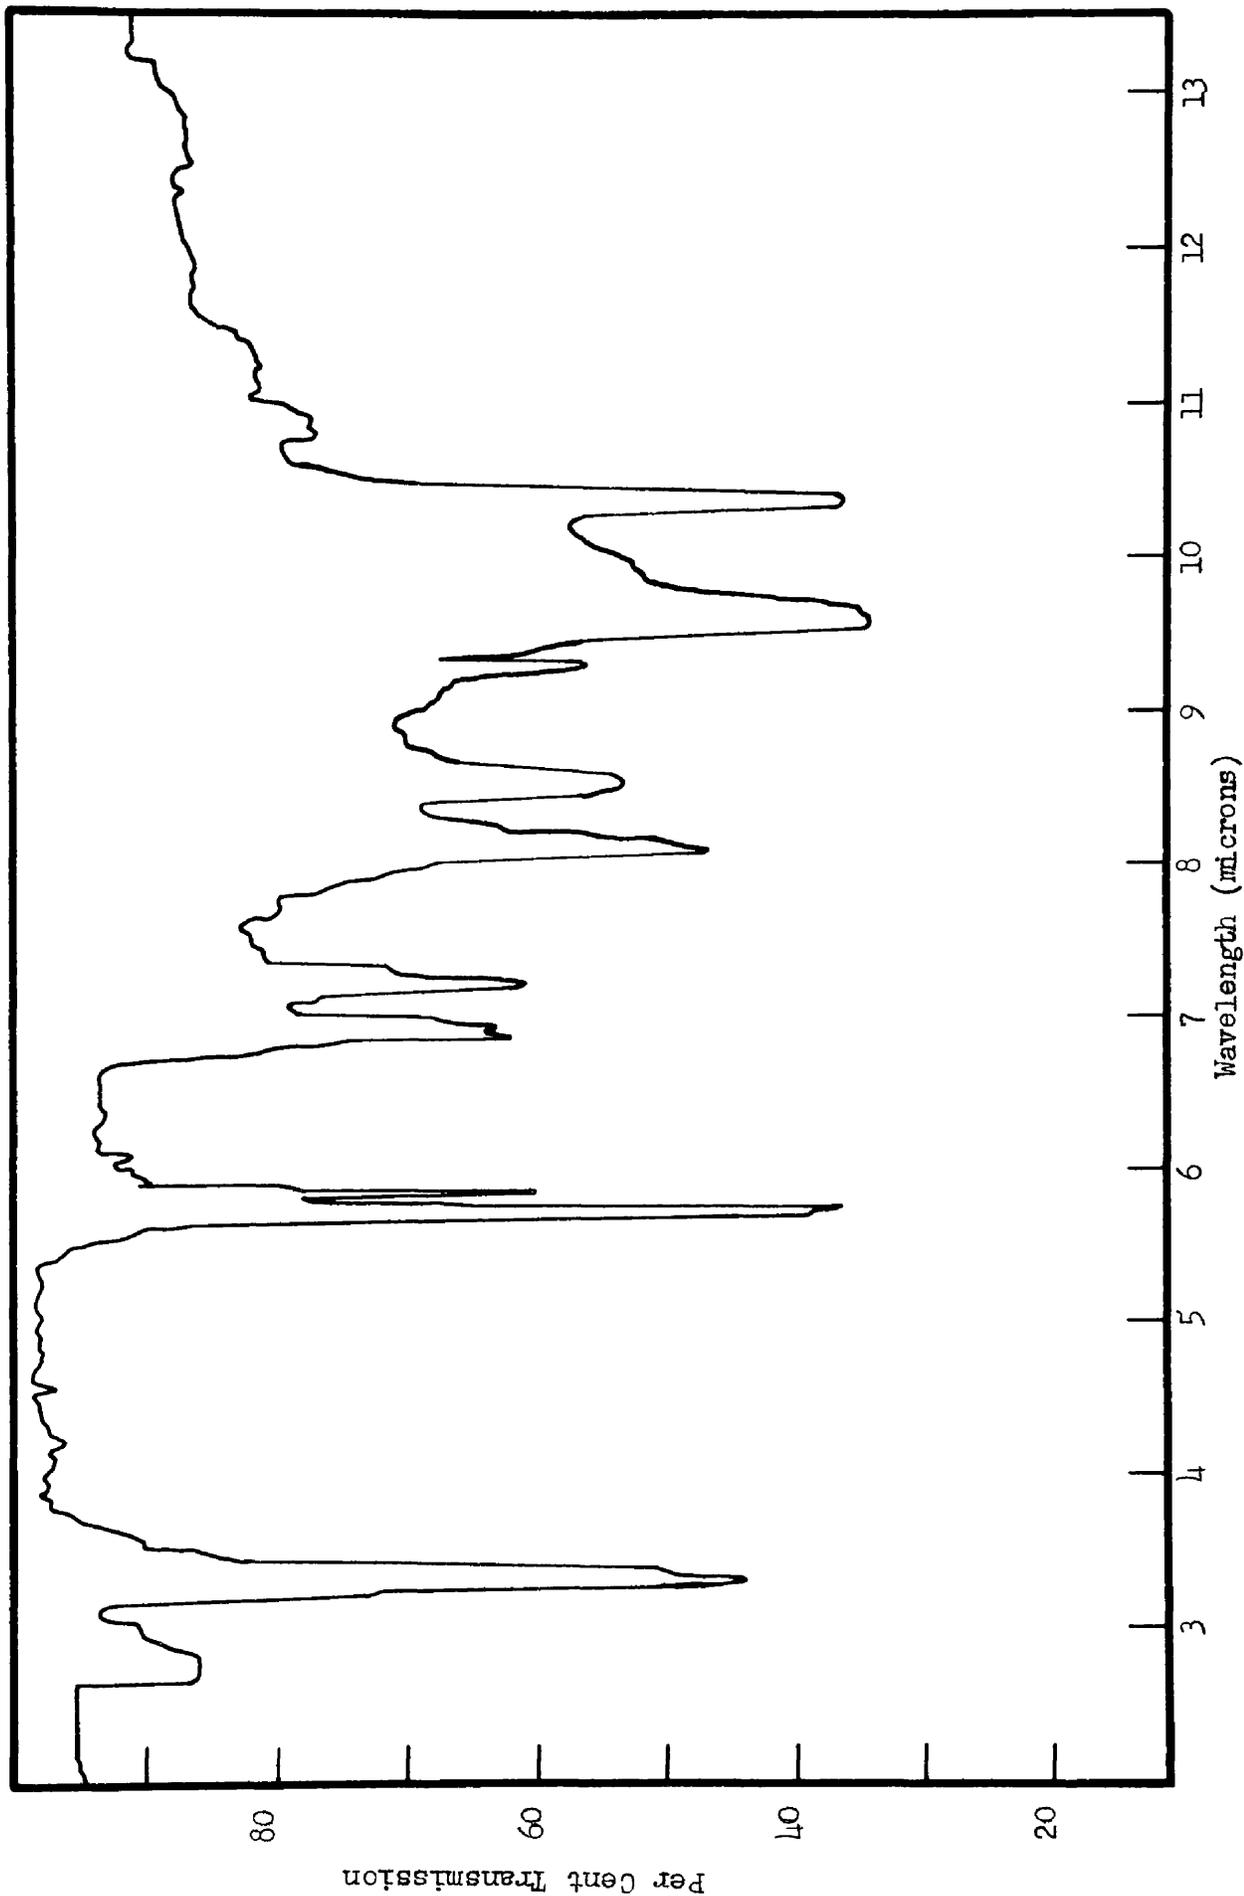

Figure 8. Infrared Spectrum of Chromic Acid Oxidation Product of 2-Methylcyclobutanol (CCl_4 solution).

procedure was separately shown to yield cyclopropylmethyl ketone from the corresponding alcohol.

The carbon tetrachloride infrared solution was extracted with 8% sodium hydroxide. The basic solution was acidified with concentrated hydrochloric acid and extracted with carbon tetrachloride. After drying these carbon tetrachloride solutions over Drierite, the infrared spectrum showed no separation of the original carbonyl absorption peaks.

The carbon tetrachloride solutions did not give a Fuchsin-Aldehyde test, although isovaleraldehyde, under similar conditions, gave a positive test.

Chromium trioxide in pyridine oxidation of 2-Methylcyclobutanol (22,23)

To 17 ml. of pyridine, which had been dried over magnesium sulfate and distilled, was added slowly 1.60 g. (0.016 mole) of chromium trioxide. To this yellow complex was added dropwise with swirling over a period of twenty minutes a solution of 0.50 g. of 2-methylcyclobutanol in 8 ml. of pyridine. Within one hour the mixture was brown, and in two hours it was a very dark brown. The solution was swirled frequently for 16 hours and then 20 ml. of water added and mixed thoroughly. The aqueous solution was extracted three times with 25-ml. portions of 20% hydrochloric acid. After drying over sodium sulfate and removing the solvent the infrared spectrum (Figure 9) on the crude residue had a strong carbonyl peak at $5.75\ \mu$, another peak at $5.86\ \mu$, and a smaller peak at $5.61\ \mu$.

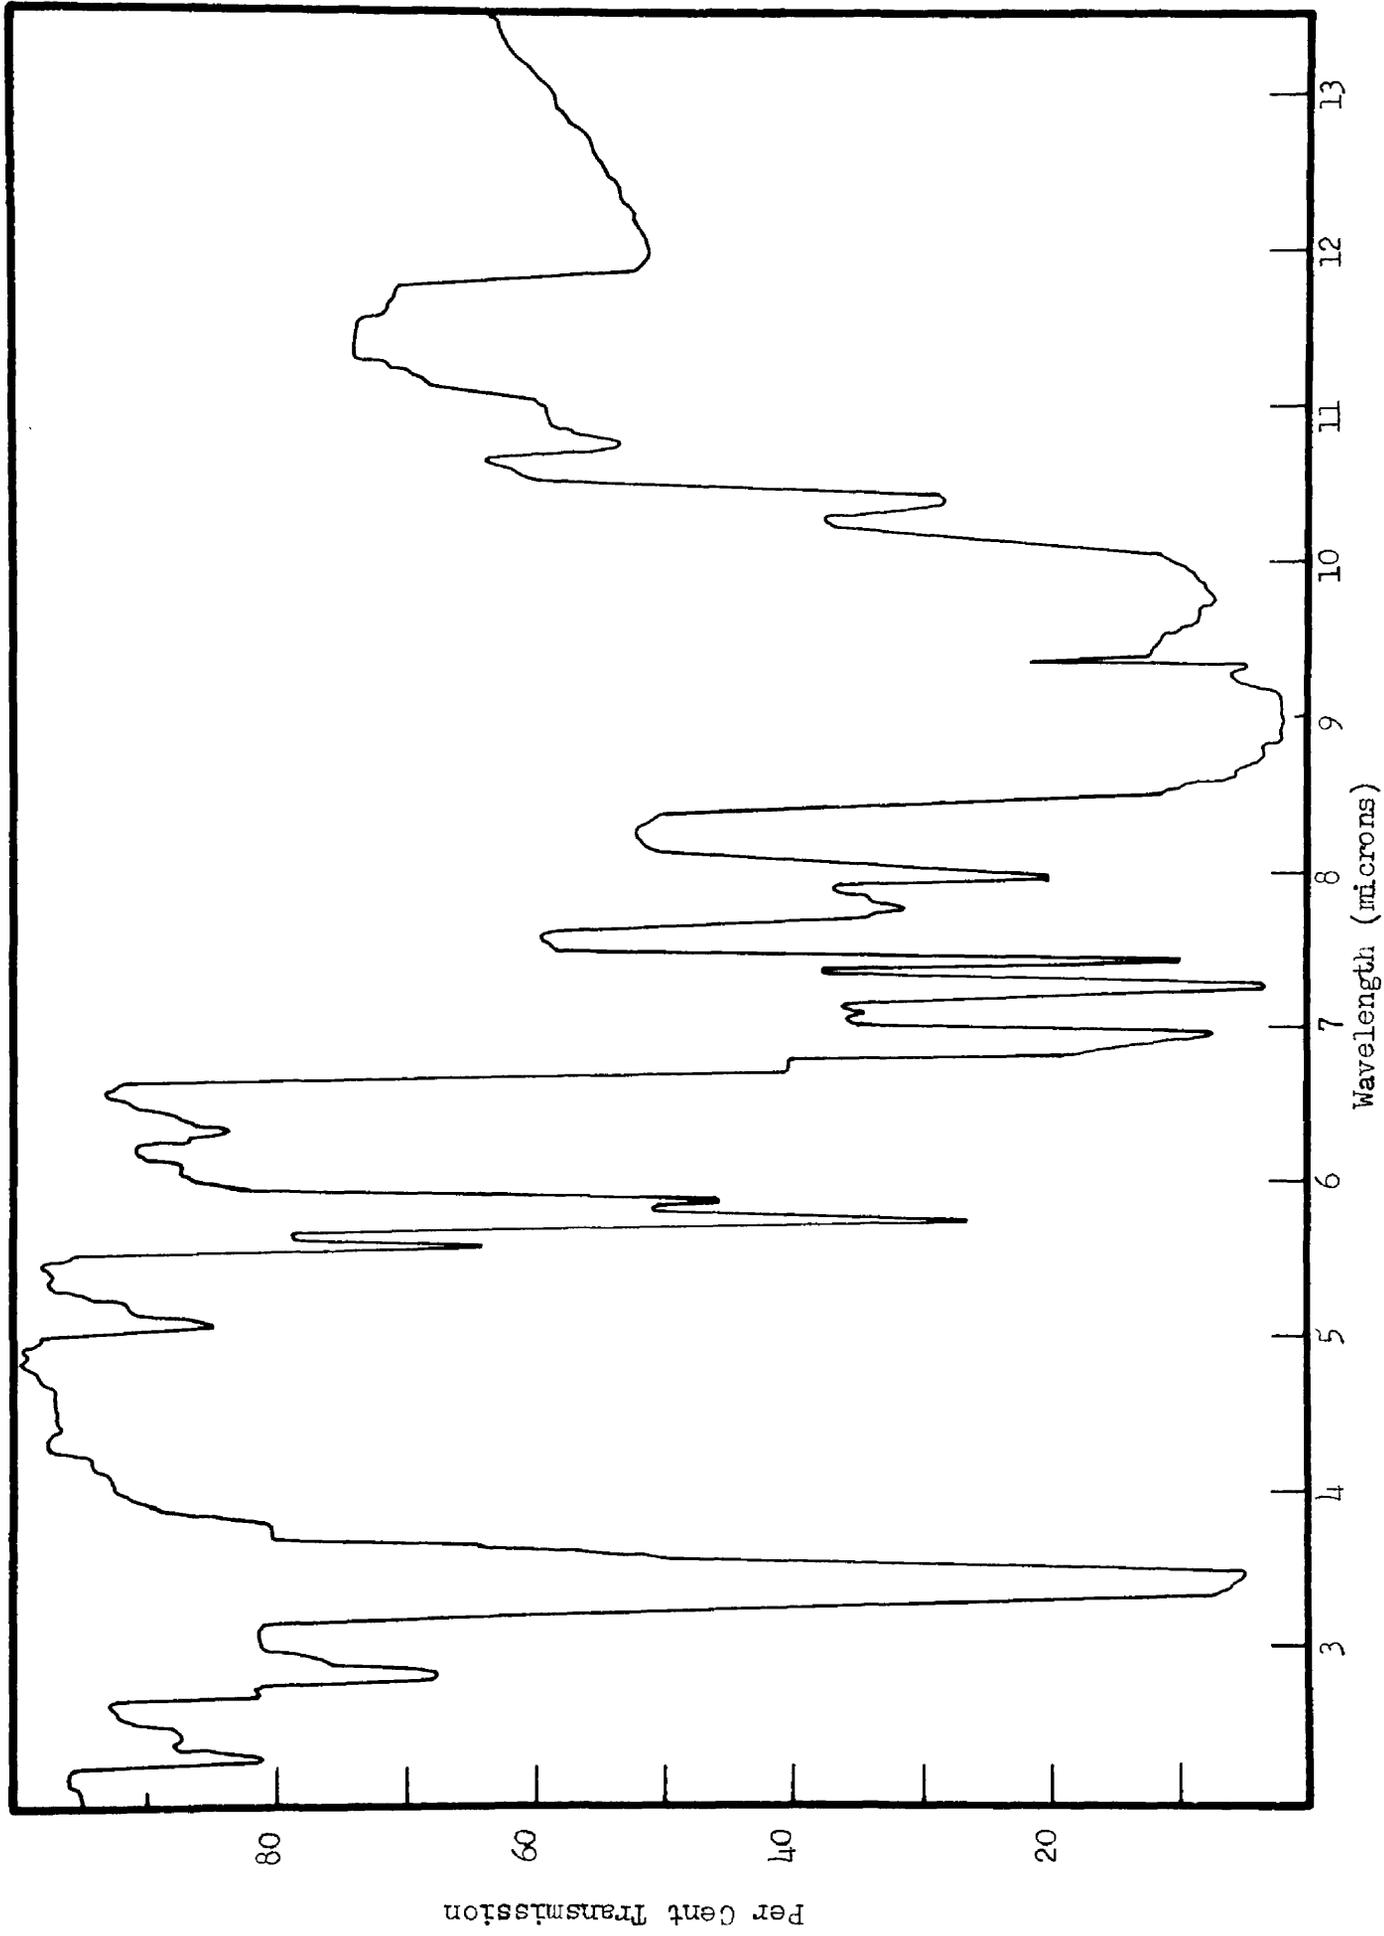

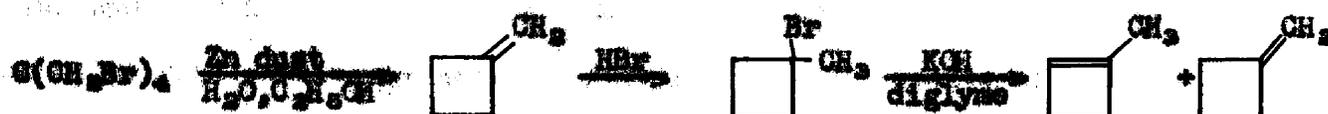

Figure 9. Infrared Spectrum of Chromium Trioxide in Pyridine Oxidation Product of 2-Methylcyclo-butanol (CCl₄ solution).

Attempted Synthesis of 2-Methylcyclobutanol

Methylcyclobutene was prepared by the method of Shand, etc. (41) according to the following reaction sequence.

The olefin mixture was fractionated through a 45 cm. tantalum wire spiral column. The fractions, b.p. 37-39°, were collected and used as methylcyclobutene (reported b.p. 37.1°). The remaining fractions, b.p. 39-42°, should be mainly methylenecyclobutane (reported b.p. 41.7°).

The diborane generator was set up as follows (45). A 300-ml. 3-necked round-bottomed flask was fitted with a nitrogen inlet, exit to a mercury safety release valve (with any exit gases then bubbling through water) and to the reaction flask containing the olefin, and a pressure equalized dropping funnel, containing 3.7 g. (0.1 mole) of recrystallized sodium borohydride (46) in 100 ml. of anhydrous diglyme. In the flask was placed 22.8 g. (0.16 mole) of freshly distilled (b.p. 122-126°) boron trifluoride-ethyl etherate in 50 ml. of diglyme.

In a 250-ml. 3-necked flask fitted with a spiral condenser connected to a water bath bubbler, and an inlet from the diborane generator so that any gas bubbled thru the solution in the flask, was placed 14.2 g. (0.21 mole) of the previously mentioned 1-methylcyclobutene in 50 ml. of anhydrous tetrahydrofuran. The flask containing the olefin was cooled in an ice-salt bath, and both flasks were stirred with magnetic stirrers. The system was flushed well with dry nitrogen.

The sodium borohydride solution was added to the boron trifluoride-ethyl etherate solution over a period of one hour to generate diborane (42). After stirring an additional hour the exit to the olefin reaction flask was disconnected and the excess diborane in the generating flask was hydrolyzed cautiously with the addition of small pieces of ice.

The olefin reaction flask was equipped with a dropping funnel and 45 ml. of 3 N sodium hydroxide was added as fast as foaming permitted. Then 25 ml. of 30% hydrogen peroxide was added over a period of one hour. The ice-salt bath was removed and stirring continued for another hour. After filtering the white solid obtained and washing it with ether, the two layers were separated and the aqueous layer extracted once with ether, and the combined organic solutions dried over magnesium sulfate.

Distillation appeared to give two main fractions. The first fraction (6.0 g.), b.p. 130-132.5°, n_D^{25} 1.4301-1.4305 gave a phenylurethane, m.p. 77.3-78.0° after several recrystallizations from hexane.

Anal. Calc'd. for $C_{12}H_{12}NO_2$: C, 70.22; H, 7.37; N, 6.93

Found: C, 70.28; H, 7.40; N, 6.88

The 3,5-dinitrobenzoate of this fraction, after several recrystallizations from 95% ethanol, had m.p. 97.5-98.5°.

Anal. Calc'd. for $C_{12}H_{12}N_2O_6$: C, 51.43; H, 4.32; N, 10.00

Found: C, 51.45; H, 4.41; N, 9.99

The second fraction, b.p. 136-139°, n_D^{25} 1.4401-1.4412 gave a phenylurethane, m.p. 111-112°. The yield of this fraction was 3.0 g.

Anal. Calc'd. for $C_{12}H_{12}NO_2$: C, 70.22; H, 7.37; N, 6.93

Found: C, 70.20; H, 7.24; N, 6.87

and a 3,5-dinitrobenzoate, m.p. 98-99°. A mixed melting

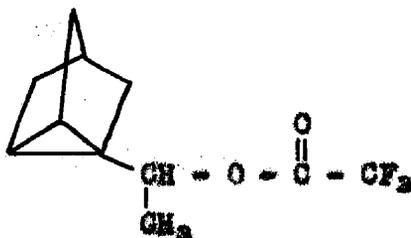

Anal. Calc'd. for $C_{12}H_{12}N_2O_6$: C, 51.43; H, 4.32; N, 10.00

Found: C, 51.44; H, 4.41; N, 9.95

point of the 3,5-dinitrobenzoates was 72-81°. The reported melting point of the phenylurethane of cyclobutylcarbinol is 65.0-66.5° and of its 3,5-dinitrobenzoate is 98.5-99.5° (47). The reported melting point of the phenylurethane of 1-methylcyclobutanol is 139.9° (41). Neither of the alcohols obtained in this synthesis correspond to these cyclobutane derivatives.

The infrared spectrum of neither of the alcohols obtained in this reaction is similar to that of the alcohol obtained from rearrangement in this thesis. Lucas tests on these fractions indicate that the lower boiling alcohol is tertiary and that the higher boiling alcohol is primary. A Lucas test on the purported 2-methylcyclobutanol indicated that it is a secondary alcohol.

Methylnortricyclylcarbinyl trifluoroacetate

This ester was prepared by a method analogous to that for cyclopropylcarbinyl trifluoroacetate. Methylnortricyclylcarbinol (6.80 g., 0.049 mole) in 25 ml. of anhydrous ether was added to 1.2 g. (0.05 mole)

of sodium hydride in 25 ml. of ether. A solution of trifluoroacetyl chloride in 90 ml. of ether, prepared from 20 g. of trifluoroacetic acid and 40 g. of benzoyl chloride and heated below 30° for two hours, was added in twenty-five minutes. Distillation of the crude product gave 6.4 g., b.p. $82-83^{\circ}$ at 13 mm., n_D^{25} 1.4506. Solvolysis studies indicated the presence of more than one component. The esterification product was fractionated through a fifteen-inch vacuum-jacketed Vigreux column, b.p. $80.5-83.1^{\circ}$ at 12 mm., n_D^{25} 1.4448-1.4560. A center fraction was sent out for analysis. Figure 10 is the infrared spectrum of this fraction.

Anal. Calc'd. for $C_{11}H_{12}F_3O_2$: C, 56.40; H, 5.59

Found: C, 60.84, 60.95; H, 6.61, 6.71

Attempts to purify the ester by vapor chromatography were unsuccessful. No conductance peaks were observed on the recorder and no ester could be obtained from the exit of the vapor chromatograph.

Miscellaneous esters of Cyclopropylcarbinol

Several esters of cyclopropylcarbinol were prepared in an attempt to find a compound suitable for kinetic studies. These esters were prepared, with procedures analogous to that for cyclopropylcarbinyl trifluoroacetate, from the appropriate acid chloride and sodium cyclopropylcarbinolate. The liquid esters were fractionated and the solid esters were recrystallized from petroleum ether (b.p. $30-60^{\circ}$) or from absolute ethanol. Physical constants, yields and analyses are given in Table I.

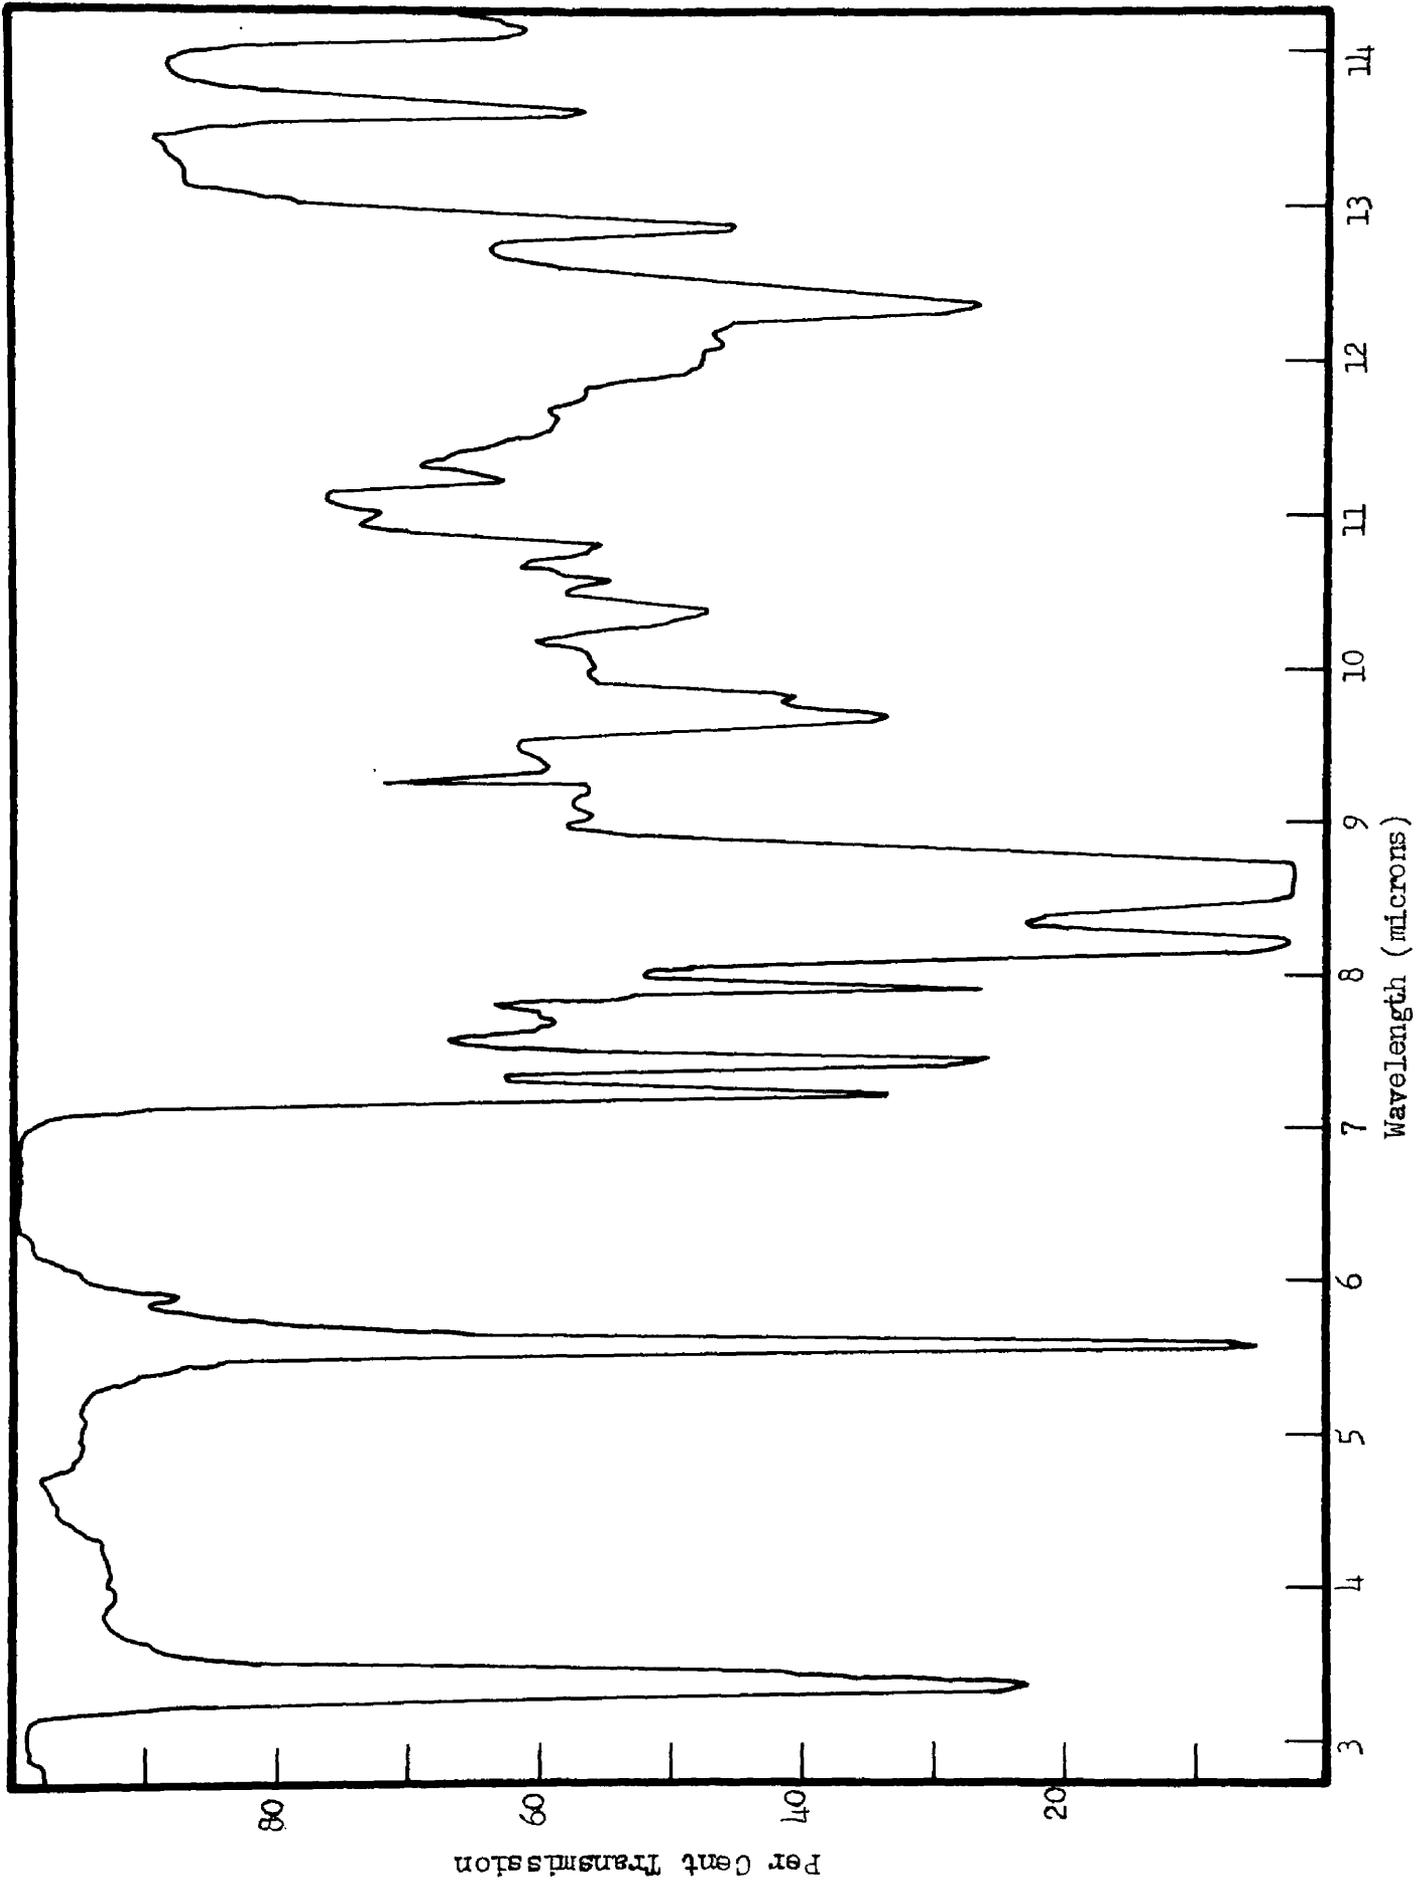

Figure 10. Infrared Spectrum of Methylnortricyclicarbonyl Trifluoroacetate (CS_2 solution).

B. Solvolysis Studies

Solvents

Dioxane was purified by the method of Fieser (24). Conductance water supplied by Dr. James L. Eyring was employed for making up solvent mixtures. The resistance of the conductance water and of the solvent mixtures was so high that it could not be measured with the conductance bridge that was used.

Methanol was purified by distillation over magnesium methoxide.

The kinetic studies and product analyses were carried out in water-dioxane solvents of several weight per cent compositions. Product analysis for three of the esters was also carried out in methanolic dioxane or in absolute methanol.

Preliminary Kinetic Studies

Several esters of cyclopropylcarbinol were prepared and the kinetic analyses of Hart and Sandri (12) by titration of the liberated acid with standard base was attempted. The nitrobenzoates and the mono- and dichloroacetates showed no appreciable solvolysis in 90 or 70% dioxane at 70° after sixty hours. With the trichloro- and trifluoroacetates the phenolphthalein end point faded, so that definite values could not be obtained.

Kinetic Procedure

The reaction was followed by noting the increase in conductance of approximately 0.025-0.050 molar solutions of ester in the particular

solvent, this increase being due to the liberated trifluoroacetic acid. This method was used previously for esters of trifluoroacetic acid by Hunt and Moffat (14,15,16). An Industrial Conductivity Bridge, model RC-1B, was used to follow the change in conductance. Kinetic runs were performed in either of two conductance cells (platinized platinum electrodes) that had cell constants of 0.1808 and 0.1160 and volumes of approximately 25 ml. The cells were placed in a constant temperature bath maintained at $\pm 0.1^\circ$ of the desired temperature.

The aqueous dioxane was equilibrated in the constant temperature bath before each run. Approximately 0.0006 mole of the ester was accurately weighed into the dry conductance cell and the cell equilibrated in the constant temperature bath. At zero time, a 25-ml. aliquot of the equilibrated solvent was pipetted into the conductance cell containing the ester and the solution was thoroughly mixed. At various time intervals the resistance of the solution was determined with the conductance bridge. The infinity resistance value was obtained by allowing the cell to remain in the bath until the resistance reading remained constant over a period of several hours. Usually 15 to 25 points were taken for each run.

Tables containing the results of the kinetic experiments are given in the Appendix which appears at the end of this thesis.

Product Analysis

(a) Solvolysis of cyclopropylcarbinyl trifluoroacetate in 70% dioxane-30% water at 60° .

Cyclopropylcarbonyl trifluoroacetate (8.4 g., 0.050 mole) was dissolved in 100 ml. of 70% dioxane-30% water and maintained at 60° for 60 hours. After cooling, the solution was saturated with sodium hydroxide and the two layers that appeared were separated. The dioxane layer was again treated with sodium hydroxide and the layers separated. The dioxane solution was then dried over Drierite, filtered and distilled until about 5 ml. remained. An infrared spectrum on this crude residue had no carbonyl or carbon-carbon double bond peaks but did have peaks ascribable to an alcohol and a cyclopropane ring (at 3.24 μ). Vapor chromatography indicated that only dioxane and cyclopropylcarbinol (Anal., 13 min.) were present.

(b) Solvolysis of cyclopropylcarbonyl trifluoroacetate in 70% dioxane-30% methanol at reflux.

Cyclopropylcarbonyl trifluoroacetate (8.4 g., 0.05 mole) was dissolved in 200 ml. of 70% dioxane-30% methanol and refluxed for 48 hours. After cooling, the solution was fractionated through a 13-inch Fenske column. The infrared spectrum of the first fraction had a carbonyl absorption peak at about 5.6 μ , similar to the carbonyl absorption of all of the trifluoroacetates. Vapor chromatography on this fraction had a conductance peak (Anal., 2.5 min.) analagous to that of authentic methyl trifluoroacetate (14). The later fractions, containing mostly dioxane, also had present cyclopropylcarbinol (Anal., 13 min.) and the original ester (Anal., 9 min.) as indicated by vapor chromatography and infrared.

(c) Attempted solvolysis of cyclopropylmethylcarbonyl trifluoroacetate in water at 50°.

Cyclopropylmethylcarbonyl trifluoroacetate (3.00 g., 0.016 mole) was heated with 10 ml. of water at 50° for twenty-four hours. As the ester was insoluble in the water, the mixture was swirled frequently. After cooling, the solution was extracted three times with 15 ml.-portions of ether and the combined ether extracts dried over sodium sulfate. After removing the solvent, infrared analysis and vapor chromatography indicated that very little solvolysis had occurred and that more of 2-methylcyclobutyl trifluoroacetate was present than was in the starting ester.

(d) Solvolysis of cyclopropylmethylcarbonyl trifluoroacetate in 60% acetone-40% water (by volume) at reflux.

Cyclopropylmethylcarbonyl trifluoroacetate (3.0 g., 0.016 mole) was dissolved in 15.0 ml. of acetone and 10.0 ml. of water was added. The solution was heated at reflux for eighteen hours, and then distilled until most of the acetone was removed. After cooling, the aqueous solution was extracted three times with 20 ml.-portions of ether and dried over magnesium sulfate. Most of the ether was removed and the residue put through the vapor chromatograph (Prep. O, 50°, 5 p.s.i. of nitrogen). Four fractions were collected. Infrared analysis indicated that fraction one (Prep. O, 10 min.) was diethyl ether.

The infrared spectrum of fraction two (Prep. O, 39-57 min.) contained absorption peaks characteristic of an alcohol, the cyclopropane ring,

the trifluoroacetate carbonyl and the carbon-carbon double bond. The infrared spectra of fraction three (Prep. C, 66-100 min.) and of fraction four (Prep. C, 110-140 min.) were almost identical and were very similar to the spectrum of 2-methylcyclobutanol. No bands characteristic of cyclopropylmethylcarbinol or its trifluoroacetate were present in the spectra of these last two fractions.

(e) Solvolysis of cyclopropylmethylcarbinyl trifluoroacetate in methanolic dioxane and in methanol at reflux.

This ester (15.0 g., 0.08 mole, with an estimated impurity of less than 10% of 2-methylcyclobutyl trifluoroacetate) was mixed with 100 ml. of 70% dioxane-30% methanol and refluxed for 24 hours. After fractionation through a 45 cm. tantalum wire spiral column, index of refraction and infrared analysis indicated that the products were mainly methyl trifluoroacetate and 2-methylcyclobutanol, plus some ester which appeared to be mainly the rearranged ester. No cyclopropylmethylcarbinyl methyl ether was observed, which should have been formed if alkyl-oxygen fission had occurred.

After refluxing 10.0 g. (0.06 mole) of approximately 90% pure cyclopropylmethylcarbinyl trifluoroacetate in 50% dioxane-50% methanol for 12 hours and then fractionating the solution through the wire spiral column, infrared analysis showed that the main products were methyl trifluoroacetate, 2-methylcyclobutanol and some rearranged ester. But a small amount of cyclopropylmethylcarbinyl methyl ether was also shown to be a product by comparison with the infrared spectrum of an authentic sample (11).

The ester (5.0 g., 0.03 mole) was also refluxed for 12 hours in absolute methanol and then fractionated. Analysis of these fractions showed that methyl trifluoroacetate and cyclopropylmethylcarbonyl methyl ether were the main products and were formed in approximately equal amounts. 2-Methylcyclobutanol was also identified.

(2) Solvolysis of 2-methylcyclobutyl trifluoroacetate in methanol at reflux.

This ester (3.2 g., 0.02 mole, 99% pure) was refluxed for 12 hours with methanol and then fractionated. Methyl trifluoroacetate (2.18 g., 95% yield) and 2-methylcyclobutanol were the only detectable products of solvolysis.

RESULTS AND DISCUSSION

A. The Attempted Structure Proof of 2-Ethylcyclobutyl Trifluoroacetate

This ester, obtained from the reaction of cyclopropylmethylcarbinol with trifluoroacetyl chloride or trifluoroacetic acid, had the same analysis as cyclopropylmethylcarbinyl trifluoroacetate, but different infrared and near infrared absorption spectra. The absence of bands at 1.65 μ and at 3.21 μ indicated that it did not contain a cyclopropane ring. Hydrolysis with base gave an alcohol whose boiling point (130-131°) and infrared spectrum were different from those of cyclopropylmethylcarbinol (b.p. 122°). A Lucas test indicated that it was a secondary alcohol. There was no carbon-carbon double bond absorption peak in the infrared spectra of the ester or the alcohol. Both of these spectra did have absorption peaks at about 10.4 μ , which may be ascribed to the cyclobutane ring (21b). The alcohol did not decolorize bromine in carbon tetrachloride, and gave a different phenylurethane (m.p. 35-41°) than cyclopropylmethylcarbinol (m.p. 69-70°). An attempt to prepare the 3,5-dinitrobenzoate gave a solid which melted below room temperature.

A search of the literature did not disclose any $C_6H_{11}O$ alcohol corresponding to the alcohol obtained from rearrangement in this thesis. The alcohol is probably 2-ethylcyclobutanol, which could have geometrical isomers, and this would account for the difficulty in preparing sharp melting derivatives.

RESULTS AND DISCUSSION

1. The Attempted Structure Proof of 2-Methylcyclobutyl Trifluoroacetate

This ester, obtained from the reaction of cyclopropylmethylcarbinol with trifluoroacetyl chloride or trifluoroacetic acid, had the same analysis as cyclopropylmethylcarbinyl trifluoroacetate, but different infrared and near infrared absorption spectra. The absence of bands at $1.65\ \mu$ and at $3.23\ \mu$ indicated that the ester did not contain a cyclopropane ring. Hydrolysis with base gave an alcohol whose boiling point ($130-131^\circ$) and infrared spectrum were different from those of cyclopropylmethylcarbinol (b.p. 122°). A Lucas test indicated that it was a secondary alcohol. There was no carbon-carbon double bond absorption peak in the infrared spectra of the ester or the alcohol. Both of these spectra did have absorption peaks at about $10.4\ \mu$, which may be ascribed to the cyclobutane ring (21b). The alcohol did not decolorize bromine in carbon tetrachloride, and gave a different phenylurethane (m.p. $39-41^\circ$) than cyclopropylmethylcarbinol (m.p. $69-70^\circ$). An attempt to prepare the 3,5-dinitrobenzoate gave a solid which melted below room temperature.

A search of the literature did not disclose any $C_6H_{10}O$ alcohol corresponding to the alcohol obtained from rearrangement in this thesis. The alcohol is probably 2-methylcyclobutanol, which could have geometrical isomers, and this would account for the difficulty in preparing sharp melting derivatives.

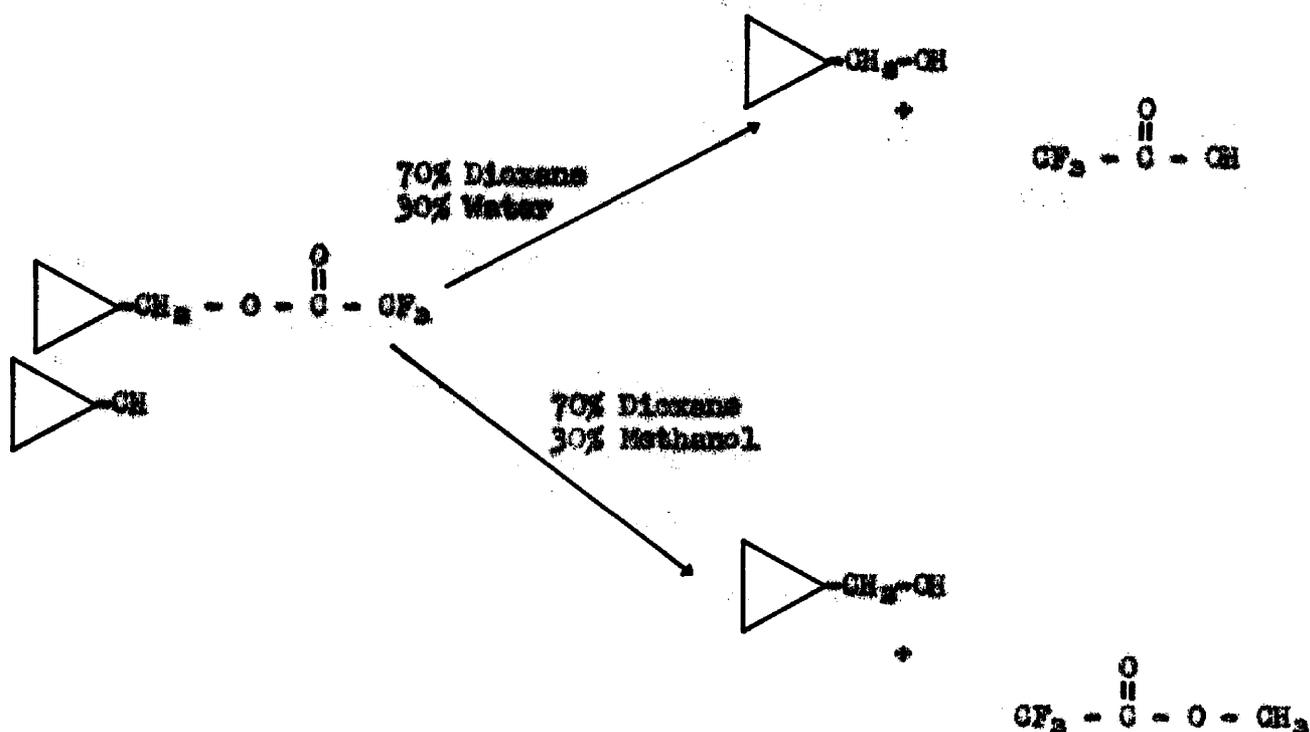

Two attempts to oxidize the alcohol to a cyclobutanone, which has a characteristic infrared carbonyl absorption at about 5.6μ (21a), were inconclusive. Both oxidations gave product with more than one carbonyl peak, and in only one case was there an absorption peak at about 5.6μ . Further oxidation of cyclobutanone derivatives with cleavage of the cyclobutane ring is not uncommon (20).

An attempt was made to synthesize 2-methylcyclobutanol from 1-methylcyclobutene, that probably had an impurity of some methylenecyclobutane. Using a new synthesis of alcohols (43,44) that is reported to give anti-Markownikoff hydration of olefins, two alcohols were obtained, neither of which corresponded to the alcohol obtained from rearrangement in this thesis. Lucas tests indicated that the synthetic alcohols were primary and tertiary, while the alcohol obtained from the rearrangement of cyclopropylmethylcarbonyl trifluoroacetate was a secondary alcohol. The primary and tertiary alcohols did not correspond to the known cyclobutylcarbinol and 1-methylcyclobutanol. Either the starting olefin did not have the expected structure, or this synthesis of alcohols does not proceed in the normal fashion on cyclobutane derivatives.

B. The Solvolysis Products

Solvolysis of cyclopropylcarbonyl trifluoroacetate in 70% dioxane-30% water at 60° gave cyclopropylcarbinol, identified by vapor chromatography and by its infrared spectrum. There was no evidence of olefin formation. When the water was replaced with methanol, the only

observed products were methyl trifluoroacetate and cyclopropylmethanol, again identified by vapor chromatography and infrared analysis. Formation of the ester demonstrates that solvolysis of cyclopropylmethyl trifluoroacetate proceeded by acyl-oxygen fission; this criterion has been used in numerous other cases (29a).

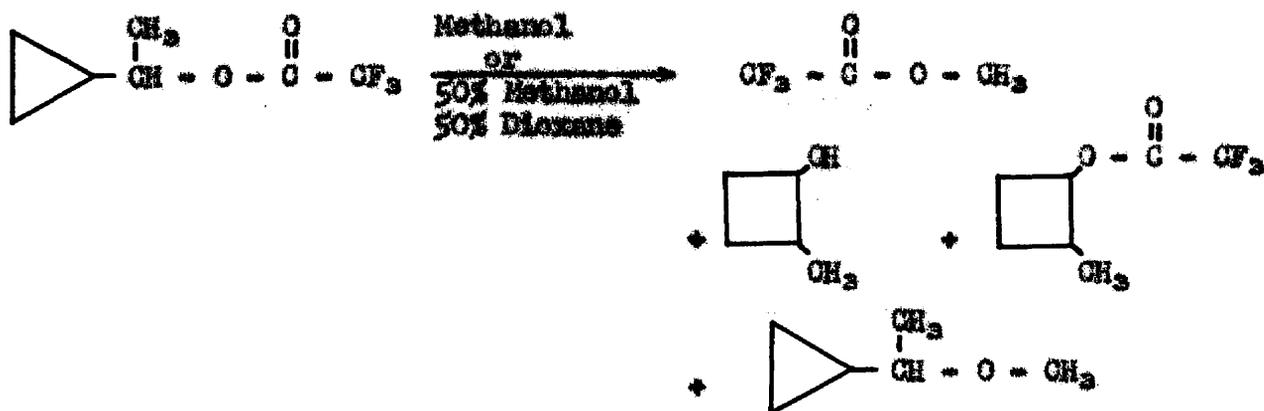

Refluxing 2-methylcyclobutyl trifluoroacetate in methanol gave only methyl trifluoroacetate and 2-methylcyclobutanol.

Although cyclopropylmethyl trifluoroacetate is not very soluble in water, an attempt was made to solvolyze this ester in water. Very little solvolysis occurred at 50° during 24 hours, but vapor chromatography on the product indicated that more 2-methylcyclobutyl trifluoroacetate was present than was in the starting ester. Also, the

main product obtained from mixing cyclopropylmethylcarbinol and trifluoroacetic acid was 2-methylcyclobutyl trifluoroacetate. Cyclopropylmethylcarbonyl trifluoroacetate was also solvolysed in 60% acetone-40% water (by volume) at reflux. Vapor chromatography and infrared analysis indicated that the products were probably cyclopropylmethylcarbinol, an unsaturated ester of trifluoroacetic acid, 2-methylcyclobutyl trifluoroacetate and 2-methylcyclobutanol.

In methanol or 50% methanolic dioxane at reflux, the products of solvolysis were methyl trifluoroacetate, cyclopropylmethylcarbonyl methyl ether, 2-methylcyclobutyl trifluoroacetate, and 2-methylcyclobutanol. More of the ether was formed in methanol than was formed in the methanolic dioxane. No ether formation was observed after refluxing in 70% methanolic dioxane. The formation of cyclopropylmethylcarbonyl methyl ether demonstrates that the solvolysis of cyclopropylmethylcarbonyl trifluoroacetate proceeded via alkyl-oxygen fission.

The 2-methylcyclobutyl trifluoroacetate presumably would arise via internal return, and this would in turn produce the methyl trifluoroacetate and the 2-methylcyclobutanol. A more complete description of

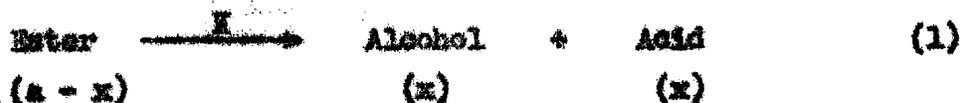

The probable mechanism of solvolysis of cyclopropylmethylcarbonyl trifluoroacetate will be given in the section on conclusions.

C. The Solvolysis Rates

The rate of solvolysis of the trifluoroacetates was measured in several weight per cent dioxane-water solutions at several temperatures. The reactions were followed by noting the decrease in resistance due to the liberation of trifluoroacetic acid and were usually followed to 50-60% completion.

Method of Calculation

The kinetic treatment is analogous to that found in Frost and Pearson (25). The solvolysis reaction may be expressed by the general equation

where

a = initial ester concentration in moles/liter

x = alcohol or acid concentration at time t

$a - x$ = ester concentration at time t .

For a first-order or pseudo first-order reaction the integrated form of the rate expression is

$$\ln (a/a-x) = kt. \quad (2)$$

The measured quantities were

R = resistance (ohms) of the solution at time t

and

R_{∞} = resistance (ohms) of the solution after it had remained constant over a period of several hours.

Since concentration is directly proportional to conductance which in turn is inversely proportional to resistance, then

$(a-x)$ is proportional to $(1/R_{\infty} - 1/R)$

and

(a) is proportional to $(1/R_{\infty} - 1/R_0)$

where

R_0 = resistance (ohms) of the solvent and ester at time zero.

Then, substituting into equation (2)

$$\ln(a/a-x) = \ln\left(\frac{1/R_{\infty} - 1/R_0}{1/R_{\infty} - 1/R}\right) = \ln\left(\frac{R}{R-R_{\infty}}\right)\left(\frac{R_0-R_{\infty}}{R_0}\right) = kt \quad (3)$$

After converting to base 10 logarithms and separating terms, the expression becomes

$$\log (R/R-R_{\infty}) = (k/2.3) t + \log (R_0/R_0-R_{\infty}) \quad (4)$$

From equation (4) it is seen that a plot of $\log (R/R-R_{\infty})$ versus t for a first order reaction should give a straight line, the slope of which is equal to $(k/2.3)$ and whose intercept is $\log (R_0/R_0-R_{\infty})$. The slopes of all lines obtained in this thesis were calculated by the method of least squares (26a,27).

Some non-linearity of the plots of $\log (R/R-R_{\infty})$ versus t might be expected due to curvature of the plot of specific conductance versus

acid concentration. Corrections for this curvature were considered to be unnecessary because the concentration of the liberated acid was small and because the inherent errors in such a correction are fairly large. Also, the plots of $\log (R/R_0)$ versus t were observed to be linear.

Comparison of Solvolysis Rates

The values of the solvolysis rate constants for the esters under various conditions are listed in Tables 2, 3, 4 and 5. The value of the specific rate constant is the arithmetic mean of all rate constants obtained for each set of conditions. Where more than one determination was made for a given solvent and temperature the standard deviation (26b) from each mean value is also given. All of the kinetic data are given in Tables 9 to 75 in the Appendix.

For a comparison of the rate constants reported in this thesis with those reported by Moffat and Hunt (14,15,16), n-butyl trifluoroacetate was prepared and solvolyzed in 70% acetone-30% water (by volume, the solvent used by Moffat and Hunt) and in 70% dioxane-30% water (by weight, a solvent used in the kinetic studies in this thesis). A value of the specific rate constant of $6.1 \times 10^{-5} \text{ sec}^{-1}$ at 45° in aqueous acetone was obtained, compared with the reported value of $5.5 \times 10^{-5} \text{ sec}^{-1}$. The rate constant for this ester in the aqueous dioxane solvent at 45° was $4.7 \times 10^{-5} \text{ sec}^{-1}$. Thus, cyclopropylcarbonyltrifluoroacetate ($k = 7.1 \times 10^{-5} \text{ sec}^{-1}$ at 45°) and n-butyl trifluoroacetate both solvolyze at about the same rate.

| 50 | 44.4 | 4.71 ± 0.03 | 1.96 |
| 60 | 106 | 12.5 ± 0.4 | 6.81 |

Typical plots of the data are shown in Figures 11, 12 and 13.

In these graphs the data for cyclopropylcarbonyl (Figure 11) and cyclopropylmethylcarbonyl (Figure 12) trifluoroacetates in 60, 70 and 80% aqueous dioxane are compared. Figure 13 is a plot of the data for four of the esters under the same conditions.

Some of the solvolysis data are compared in Table 6. It is evident from this table that the trifluoroacetates of cyclopropylcarbinol, nortricyclohexylcarbinol and 2-methylcyclobutanol all solvolyse at about the same rate, while the trifluoroacetates of cyclopropylmethylcarbinol and methylnortricyclohexylcarbinol solvolyse somewhat faster.

Cyclopropylmethylcarbonyl and 2-Methylcyclobutyl trifluoroacetates

In the preparation of cyclopropylmethylcarbonyl trifluoroacetate two esters were obtained. A typical plot of the kinetic data obtained from the mixture of these two esters, as obtained from the esterification of cyclopropylmethylcarbinol, is shown in Figure 14 (curve A). The esters were separated using vapor chromatography, and kinetic data on the separate esters were also obtained.

An attempt was made to analyze the kinetic data of the esterification mixture into the individual solvolysis rate constants. Satisfactory rate constants were obtained only for the slower solvolyzing ester, 2-methylcyclobutyl trifluoroacetate. The latter portion of the plots of $\log (R/R_\infty)$ versus t were linear (see Figure 14) and from the slope of this portion of the graphs, which represents the solvolysis of the slow ester, rate constants for the solvolysis of 2-methylcyclobutyl

Figure 14. Plot of $\log(R/R_*)$ versus t for the Solvolysis of Mixtures Obtained from the Esterification of Cyclopropylmethylcarbinol and Methyl-nortricyclylcarbinol in 70% Aqueous Dioxane at 50° . Data from Tables 49 and 64.

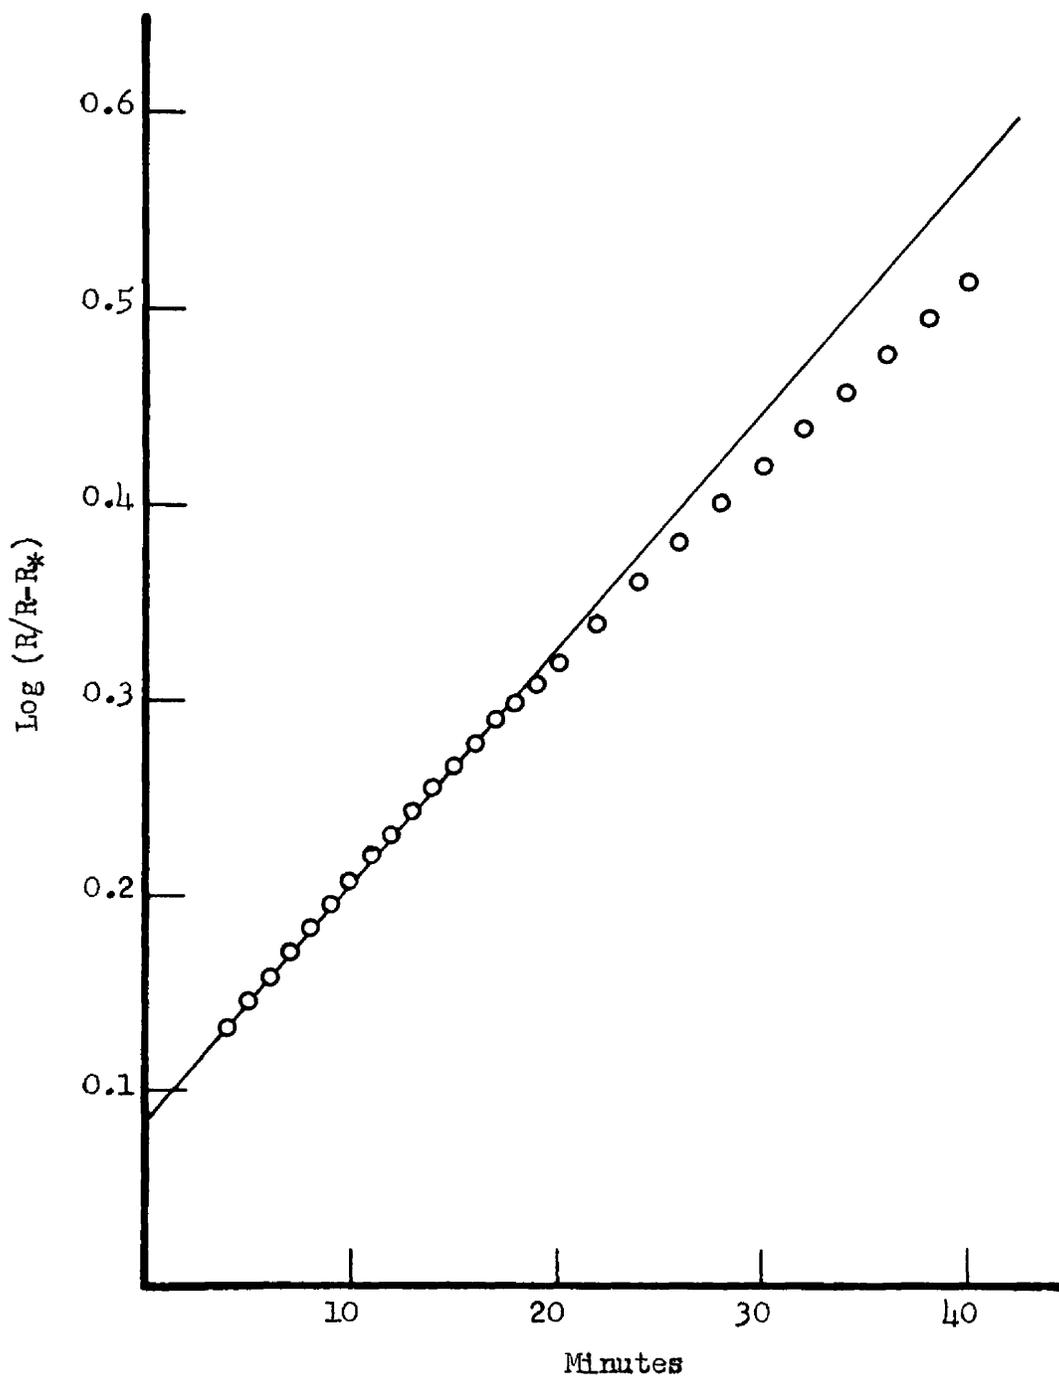

trifluoroacetate (which agreed within 10% with those obtained from studies on the pure ester) were calculated. Rate constants for this ester in 60% aqueous dioxane (Table 4) were all obtained in this manner, whereas those in 70% dioxane were obtained on the pure ester.

Rate constants for the solvolysis of cyclopropylmethylcarbonyl trifluoroacetate (the initial portion of the data) calculated from the kinetic data of the esterification mixture were about 50-100% slower than those obtained with the pure ester. The method used for these rate constants was the same as that given later for methylcyclopropylmethylcarbonyl trifluoroacetate. The rate constants reported for cyclopropylmethylcarbonyl trifluoroacetate (Table 5) are those obtained on the pure ester.

Even when pure (at least 98%) cyclopropylmethylcarbonyl trifluoroacetate was solvolyzed, the plotted data (see Figure 15) frequently had a slight curvature. This curvature was most evident in the higher per cent dioxane solvents and at the lower temperatures; it was not observed in the lower per cent dioxane solvents at the higher temperatures. In all cases, the reported rate constants are only from that portion of the data that gave the initial straight line. A minimum of about 35-40% of the reaction (in 80% dioxane at 40°) and a maximum of about 90% of the reaction (in 60% dioxane at 60°) was used in calculating the reported rate constants. This curvature of the kinetic data for this ester is probably due to internal return of the cyclopropylmethylcarbonyl trifluoroacetate to 2-methylcyclobutyl trifluoroacetate which then solvolyzes at a measurable, but slower, rate than the original ester.

Figure 15. Plot of $\log(R/R-R_*)$ versus t for the Solvolysis of Cyclopropylmethylcarbonyl Trifluoroacetate in 70% Aqueous Dioxane at 50° . Data from Table 57.

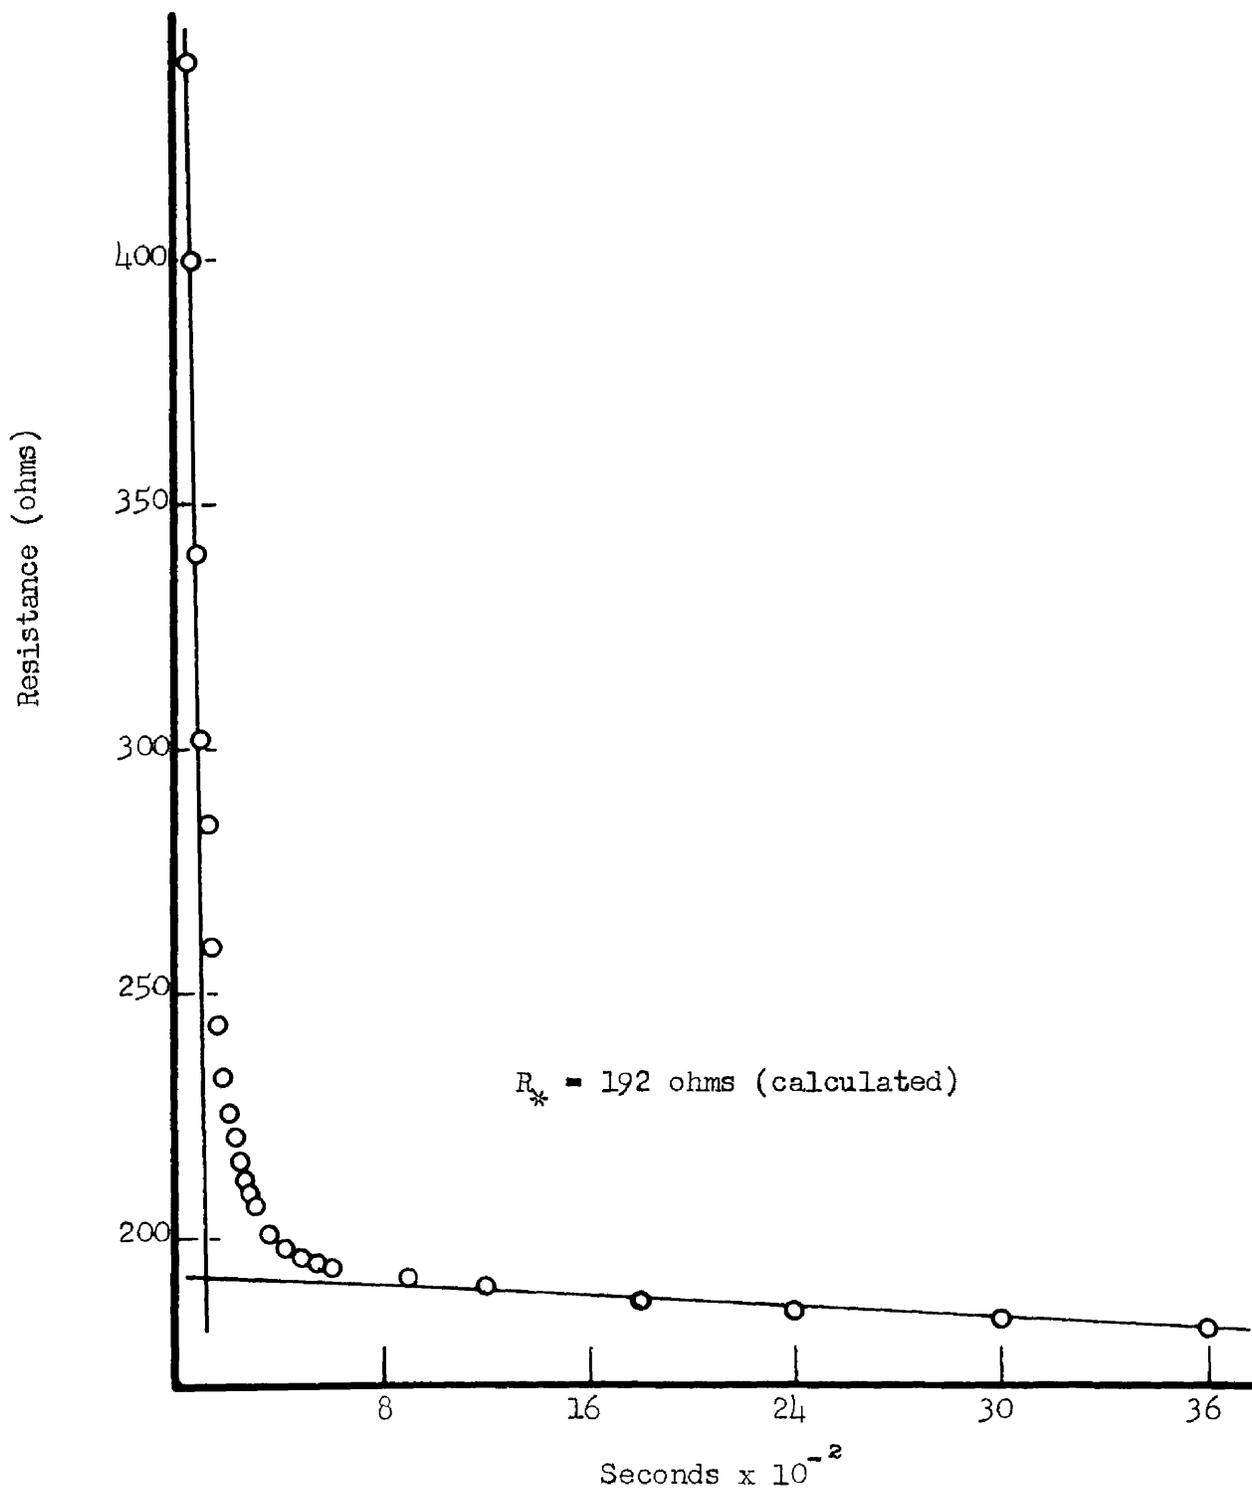

Methylnortricyclylcarbonyl trifluoroacetate

Kinetic analysis of the distilled reaction mixture from the preparation of methylnortricyclylcarbonyl trifluoroacetate also gave curved plots (see Figure 14, curve B). The kinetic plots for this ester had much sharper breaks than those for cyclopropylmethylcarbonyl trifluoroacetate. The product could not be purified by fractionation or by vapor chromatography. A carbon and hydrogen analysis on a sample did not agree with the calculated values.

By analogy with kinetic studies on the esterification mixture of cyclopropylmethylcarbinol, the faster solvolysing ester in this case is probably methylnortricyclylcarbonyl trifluoroacetate. Rate constants for the initial portion of the data were calculated in the following manner. From a plot of resistance versus time (see Figure 16) a calculated R_{∞} was obtained by extrapolating the two approximately straight lines to their intersection. The resistance at this point was taken as the R_{∞} value for the solvolysis of the faster solvolysing ester. Using this value of R_{∞} , plots of $\log(R/R - R_{\infty})$ versus t were made which were straight lines for the first part of the kinetic data. From the slope of these lines some rate constants for the solvolysis of methylnortricyclylcarbonyl trifluoroacetate were obtained. At 50° in 70% dioxane-30% water, $k = 8.8 \times 10^{-3} \pm 0.3 \text{ sec.}^{-1}$ (four runs). Also at 50°, in 80% dioxane-20% water, $k = 3.5 \times 10^{-4} \text{ sec.}^{-1}$ (one run). No attempt was made to analyze the slopes of the latter portion of the curves.

Figure 16. Plot of Resistance versus t for the Solvolysis of Methylnortricyclylcarbinyl Trifluoroacetate in 70% Aqueous Dioxane at 50° . Data from Table 68.

D. The Energetics

The Arrhenius activation energy, E_a , was calculated in the usual manner from

$$\log k = - (E_a/2.3 R)(1/T) + Z \quad (5)$$

Plots of $\log k$ versus $1/T$ for the esters in various solvents appear in Figures 19 to 29 in the Appendix. After obtaining the slope by the method of least squares the activation energy was calculated from

$$E_a = 2.3 R (-\text{slope})$$

where $R = 1.987$ calories degree⁻¹ mole⁻¹.

The enthalpy of activation, ΔH^\ddagger , was calculated from the following equation.

$$\Delta H^\ddagger = E_a - RT \quad (6)$$

The entropy of activation, ΔS^\ddagger , was calculated from the Eyring equation (28).

$$k = \frac{k_B T}{h} e^{\Delta S^\ddagger/R} e^{-\Delta H^\ddagger/RT} \quad (7)$$

or

$$\Delta S^\ddagger = 2.3 R \log \left(\frac{k h}{k_B T} \right) + \frac{\Delta H^\ddagger}{T} \quad (8)$$

where $h =$ Planck's constant, 6.623×10^{-27} erg second

$k_B =$ Boltzmann constant, 1.380×10^{-16} erg degree⁻¹ molecule⁻¹.

Values of ΔH^* and ΔS^* for the various reactions are listed in Table 7. The ΔS^* values are the arithmetic mean of all of the ΔS^* values calculated from equation (8) for each K obtained for a given ester in each solvent. The standard deviation from each mean value is also given.

Of particular interest are the similarities of the entropies and enthalpies of activation for the trifluoroacetates of cyclopropylcarbinol, nortricycylcarbinol, and 2-methylcyclobutanol as compared to the same energy factors for cyclopropylmethylcarbonyl trifluoroacetate.

A comparison of these energy factors with those obtained in other studies is given in Table 8. The trifluoroacetates of the primary alcohols and all of the secondary aliphatic alcohols except that of cyclopropylmethylcarbinol have relatively small enthalpies and large, negative entropies. In these cases the rate of solvolysis is controlled by the high orientation requirements of solvent molecules about the trifluoroacetate carbonyl group.

The entropies and enthalpies of activation for the solvolysis of cyclopropylmethylcarbonyl trifluoroacetate are similar to those for esters of tertiary alcohols studied by Moffat and Hunt (15) and by Hart and Sandri (12). The enthalpies are large while the entropies are relatively small, but still negative. This indicates that the rate controlling factor in these cases is the cleavage of the alkyl-oxygen bond (which would have a relatively large energy requirement).

E. Conclusions

It is apparent from the experimental results that the solvolyses of the trifluoroacetates reported in this thesis proceed by two different mechanisms.

The rates, enthalpies and entropies of activation, and the products from methanolysis are all consistent with the following mechanism (29b, 30) for the solvolyses of the trifluoroacetates of cyclopropylcarbinol, nortricycylcarbinol and 2-methylcyclobutanol.

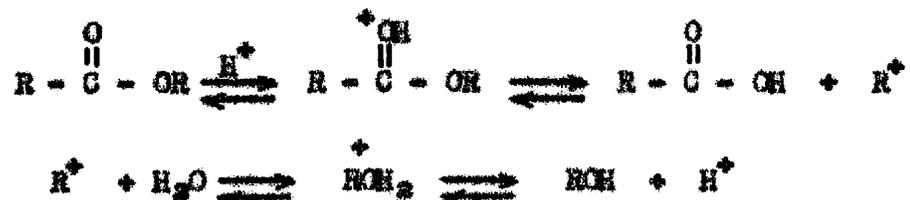

Cyclopropylmethylcarbinyl trifluoroacetate solvolyses with alkyl-oxygen fission and with simultaneous rearrangement. This was demonstrated by solvolysing this ester in methanol and showing that two of the products were cyclopropylmethylcarbinyl methyl ether and 2-methylcyclobutyl trifluoroacetate. By analogy with the work of Hart and Sandri (12) the mechanism of the solvolysis of this ester probably proceeds through an ion-pair intermediate, as summarized by the following scheme:

The proof of structure of the rearranged alcohol and measurement of the amount of rearrangement would place this postulated mechanism on a sounder basis.

In discussing the mechanism of the acid-catalyzed hydrolysis of esters of tertiary alcohols (as given below), Hine (30) has stated

that, "in order for this cleavage to occur without acid catalysis, the

carbonium ion to be formed should be more stable or the anion to be formed should be less basic, or both." From this, and considering the solvolyses of the trifluoroacetates of cyclopropylcarbinol and cyclopropylmethylcarbinol, it is evident that the stability of the secondary carbonium ion ($\triangle^+ \text{CH-CH}_3$) that is formed is sufficiently greater than the stability of the primary carbonium ion ($\triangle^+ \text{CH}_2$, that would be formed if alkyl-oxygen fission had occurred) to allow for the observed duality of mechanisms for these two esters.

It should also be noted that the secondary-alkyl trifluoroacetates studied by Moffat and Hunt (16) solvolyzed by acyl-oxygen fission. For cyclopropylmethylcarbinyl trifluoroacetate to solvolyze via alkyl-oxygen fission, the cyclopropane ring must be aiding in stabilizing the carbonium ion that is formed.

By analogy, methylnortricycliccarbinyl trifluoroacetate probably solvolyzes by the same mechanism as the trifluoroacetate of cyclopropylmethylcarbinol. The faster rate of solvolysis of the ester of methylnortricycliccarbinol may be ascribed to a greater release of steric strain or to an enhanced stability of the carbonium ion formed in this case in contrast to the trifluoroacetate of cyclopropylmethylcarbinol.

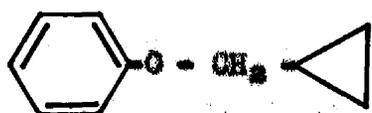

PART II

**THE SYNTHESIS AND ATTEMPTED THERMAL REARRANGEMENT
OF CYCLOPROPYLCARBENYL PHENYL ETHER**

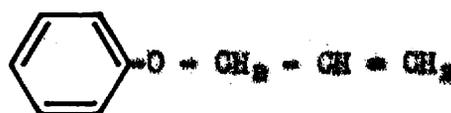

INTRODUCTION

INTRODUCTION

This part of the thesis is concerned with the synthesis and attempted thermal rearrangement of cyclopropylcarbinyl phenyl ether (I). In this ether the cyclopropane ring is in a position analogous to that of the carbon-carbon double bond in allyl phenyl ether (II).

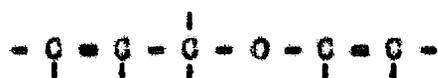

(I)

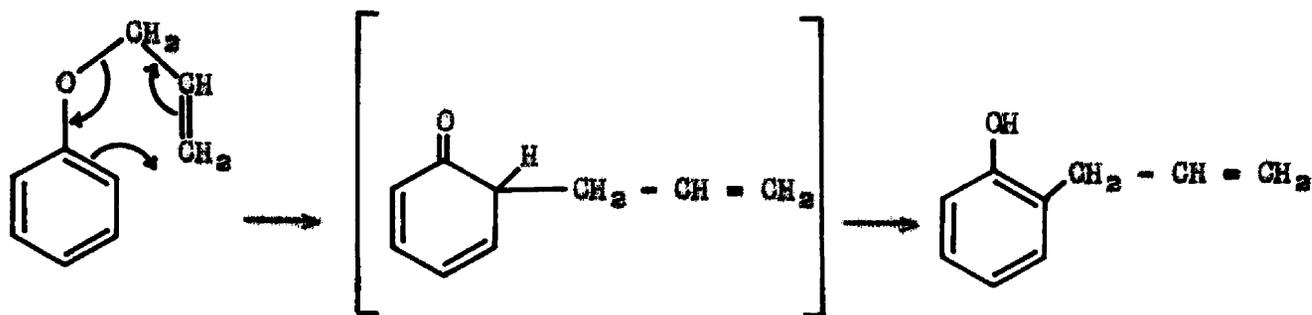

(II)

The Claisen rearrangement of allyl phenyl ethers has been extensively studied and two reviews have been written (32,33). Recent work has been concerned with the p-Claisen rearrangement (34).

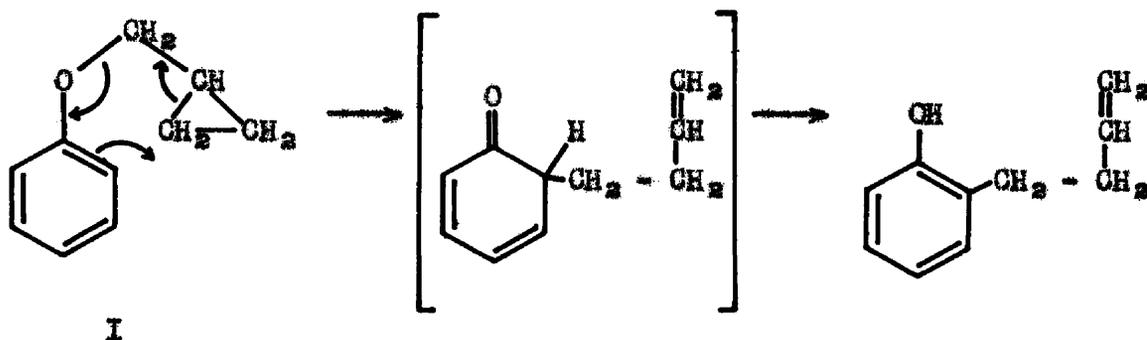

The structural arrangement of atoms necessary for the Claisen rearrangement is

The double bond on the right may be an aliphatic double bond, as in an enol ether or a vinyl ether, or part of an aromatic ring, as in the phenyl ethers (33). The rearrangement is best represented by a concerted cyclic mechanism, with the formation of a dienone intermediate which then enolizes to give the final product.

The similarities between the cyclopropane ring and the carbon-carbon double bond are well recognized (1). It was of interest, therefore, to determine whether cyclopropylcarbinyl phenyl ether (I) would undergo the Claisen rearrangement. A plausible mechanism analogous to that already demonstrated for allyl phenyl ether, and in agreement with the current concept of the cyclopropane ring, can be envisioned.

A partial increase in the positive character of the α -carbon atom of the allyl group in the Claisen rearrangement has been postulated (34). Thus, in accord with the postulated resonance structures ascribed to the cyclopropylcarbinyl system in unimolecular displacements, it was further expected that cyclopropylcarbinyl phenyl ether would undergo a Claisen rearrangement.

This part of the thesis is concerned with the synthesis and attempted thermal rearrangement of cyclopropylcarbinyl phenyl ether.

EXPERIMENTAL

A. Synthesis of Cyclopropylmethyl Phenyl Ether

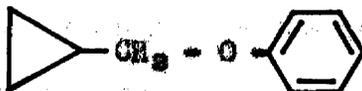

Method A. Displacement of the tosylate group by phenoxide ion (1).

A 300-ml. three-necked flask, fitted with a Harberg stirrer, reflux condenser, thermometer ~~XXXXXXXXXX~~ funnel was charged with 25.4 ml. of 2,4,6-collidine and 7.2 g. (0.1 mole) of cyclopropylmethyl and cooled to -3° in an ice-salt bath. p-Toluenesulfonyl chloride (18.0 g., 0.1 mole) in 50 ml. of methylene chloride was added in forty-five minutes, the temperature remaining below 3°. An additional 25 ml. of methylene chloride was added and stirring continued at about 0° for two hours. The collidine was neutralized with 25 ml. of 15 N sulfuric acid, the temperature remaining below 15°. The layers were separated and the aqueous layer extracted once with 25 ml. of methylene chloride. The combined methylene chloride solution was extracted three times with 20 ml. portions of ice-cold 2.5 N sulfuric acid and dried over potassium carbonate.

The solvent was removed at reduced pressure with no heat applied. The residue was a reddish oil. The red oil was dissolved in 50 ml. of anhydrous ether and added (15 minutes) to a suspension of sodium

EXPERIMENTAL

A. Synthesis of Cyclopropylcarbonyl Phenyl Ether

Method A. Displacement of the tosylate group by phenoxide ion (3).

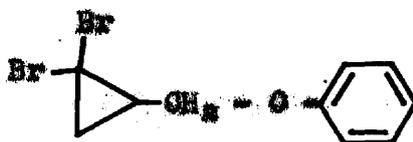

A 300-ml. three-necked flask, fitted with a Heraeus stirrer, reflux condenser, thermometer and a dropping funnel was charged with 26.4 ml. of 2,4,6-collidine and 7.2 g. (0.1 mole) of cyclopropylcarbinol and cooled to -3° in an ice-salt bath. *p*-Toluenesulfonyl chloride (19.0 g., 0.1 mole) in 50 ml. of methylene chloride was added in forty-five minutes, the temperature remaining below 3° . An additional 25 ml. of methylene chloride was added and stirring continued at about 0° for two hours. The collidine was neutralized with 25 ml. of 10 N sulfuric acid, the temperature remaining below 15° . The layers were separated and the aqueous layer extracted once with 25 ml. of methylene chloride. The combined methylene chloride solution was extracted three times with 20 ml.-portions of ice-cold 2.5 N sulfuric acid and dried over potassium carbonate.

The solvent was removed at reduced pressure with no heat applied. The residue was a reddish oil. The red oil was dissolved in 50 ml. of anhydrous ether and added (30 minutes) to a suspension of sodium

phenoxide, prepared from 250 g. of phenol and 34.5 g. (1.5 mole) of sodium in 200 ml. of ether, in a 1-l. three-necked flask fitted with a Hershberg stirrer, reflux condenser, thermometer and dropping funnel and cooled in an ice bath. The solution was then stirred at room temperature for five days. The solution was filtered and washed six times with 10% sodium hydroxide and twice with water. After removing the solvent distillation yielded 1.0 g. of cyclopropylcarbonyl phenyl ether, b.p. 45-48° at 2 mm., n_D^{25} 1.5189. It gave a negative ferric chloride test. This product was not analyzed, but it did have similar physical constants and an identical infrared spectrum with the same product prepared by a different method.

Method B. Carbene reaction on allyl phenyl ether (35).

(a) 2,2-Dibromocyclopropylcarbonyl phenyl ether (35).

Potassium tertiary butoxide (0.5 mole) was prepared from excess anhydrous tertiary butyl alcohol and 20 g. (0.5 mole) of potassium in a 2-l., three-necked flask fitted with a Hershberg stirrer, reflux condenser, thermometer and a dropping funnel. The excess tertiary butyl alcohol was removed by distillation and the potassium tertiary butoxide dried at about 100° at 1 mm. for four hours. After cooling in an ice bath and breaking up the potassium tertiary butoxide with a glass rod and with the stirrer, the white powder was covered with 165 g. (1.2 moles)

of allyl phenyl ether and 100 ml. of anhydrous pentane. Bromoform (126.5 g., 0.5 mole) was added with stirring in one hour. The mixture immediately turned orange-red and later became brown. Stirring was continued an additional five hours at room temperature, during which time an additional 200 ml. of pentane was added. After pouring into 200 ml. of water the organic layer was separated, the aqueous layer extracted once with 75 ml. of pentane and the combined pentane solutions dried over magnesium sulfate. Distillation gave recovered allyl phenyl ether (133 g.) and 41.2 g. of material, b.p. 119-126° at 1 mm. which solidified at room temperature. After several recrystallizations from ethanol the product (31.5 g., 21%) had a melting point of 53-54°.

Found: C, 39.21, 39.06; H, 3.38, 3.31; Br, 52.43, 52.47

(b) Reduction of 2,2-dibromocyclopropylcarbinyl phenyl ether (36).

A 1-l. three-necked flask was fitted with an efficient reflux condenser, Hershberg stirrer and a dropping funnel and was charged with 100 ml. of 95% ethanol, 60 g. of Raney nickel alloy and 10.0 g (0.033 mole) of 2,2-dibromocyclopropylcarbinyl phenyl ether. This mixture was treated with 600 ml. of 10% sodium hydroxide (one hour). Addition was slow at first because there was an induction period before the base began reacting with the Raney-nickel alloy. The solution was refluxed an additional two hours, filtered, and the filtrate washed with 100 ml. of 10% sodium hydroxide and then with 400 ml. of pentane. The aqueous layer was poured into 400 ml. of concentrated hydrochloric acid and then

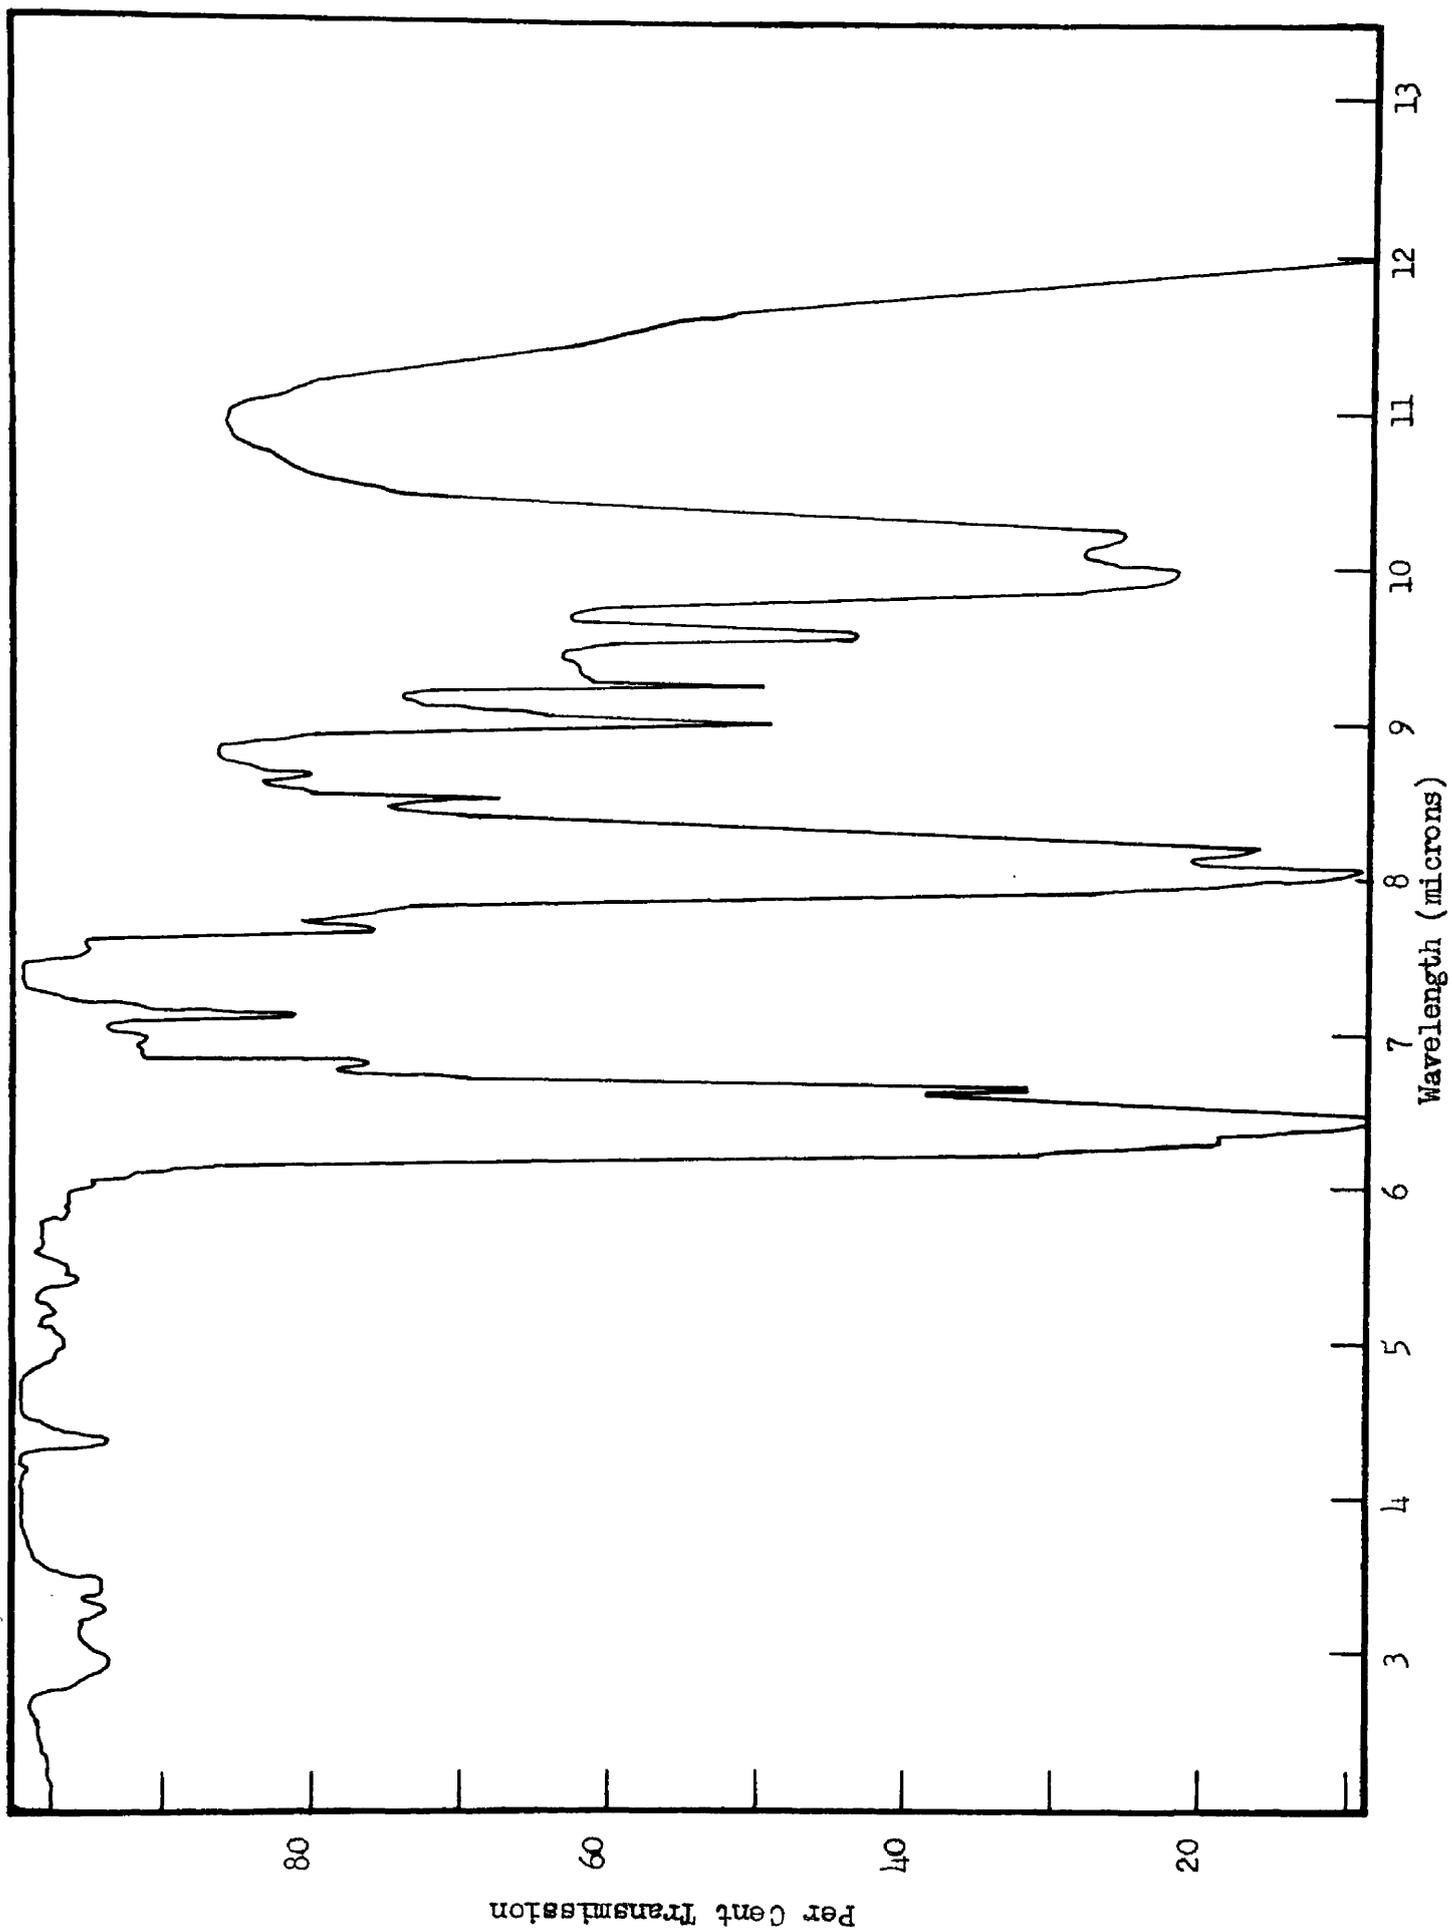

Figure 17. Infrared Spectrum of 2,2-Dibromocyclopropylcarbonyl Phenyl Ether (CCl_4 solution).

extracted two times with 100 ml.-portions of pentane. After drying the combined pentane solutions over sodium sulfate and removing the solvent the product (3.0 g., 62%) distilled at 43-55° at 2 mm.

The product from several reductions were combined and fractionated to give cyclopropylcarbonyl phenyl ether, b.p. 51-53° at 2 mm., n_D^{20} 1.5191-1.5199. It gave a negative ferric chloride test.

Anal. Calc'd. for $C_{10}H_{12}O$ C, 81.04; H, 8.17

Found: C, 81.11, 81.16; H, 8.29, 8.34

B. Attempted Thermal Rearrangement of Cyclopropylcarbonyl Phenyl Ether

One ml. of cyclopropylcarbonyl phenyl ether was refluxed (214°) at atmospheric pressure for six hours. After cooling, an infra red spectrum was obtained that was unchanged from that of the starting ether.

Refluxing this solution for an additional twelve hours also did not change the infra red spectrum.

A one-ml. portion of the ether was heated in a sealed tube, whose volume was approximately 11 ml., at $300 \pm 4^\circ$ for ten hours. The infra red spectrum of this material was identical with that of the starting ether. Both after refluxing for eighteen hours and after heating in a sealed tube the final material gave a negative ferric chloride test for phenols.

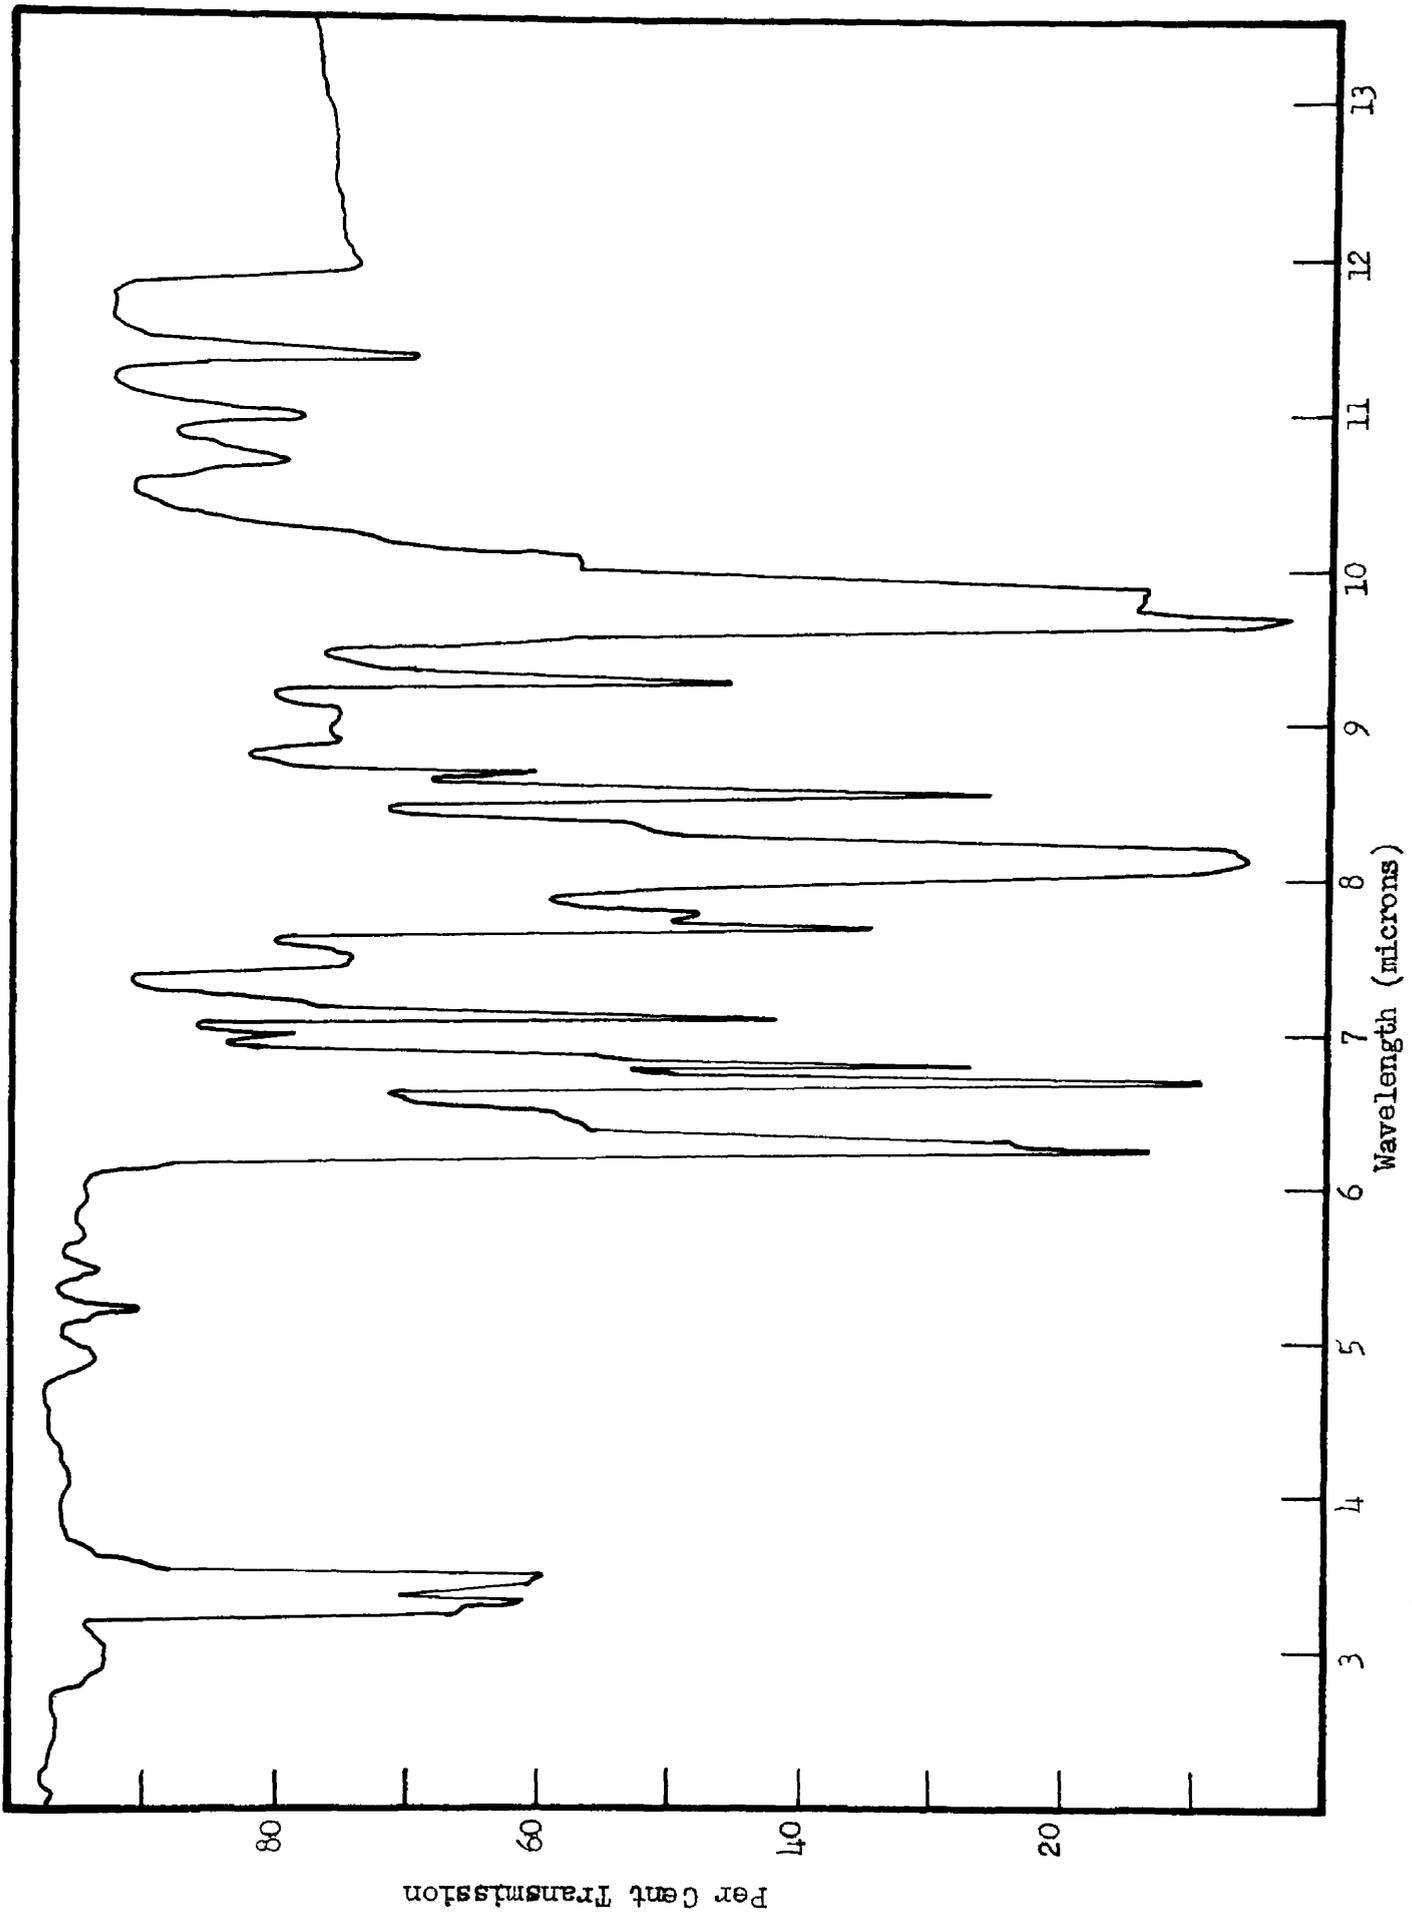

Figure 18. Infrared Spectrum of Cyclopropylcarbonyl Phenyl Ether (CCl₄ solution).

RESULTS AND DISCUSSION

12

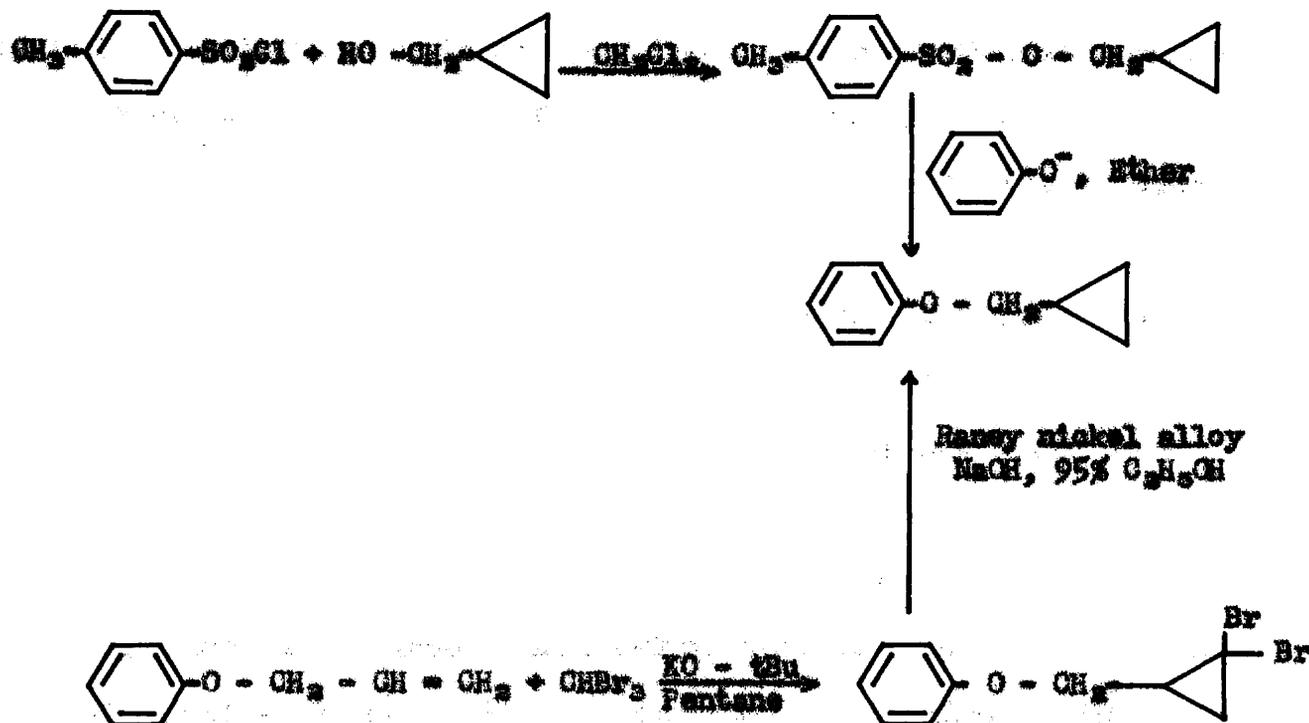

13

14

15

RESULTS AND DISCUSSION

Cyclopropylcarbonyl phenyl ether was prepared by two independent methods, as outlined in the following scheme.

Bergstrom and Siegel (3) have shown that the benzenesulfonate of cyclopropylcarbinal in ethanol gives unrearranged cyclopropylcarbonyl ethyl ether. The tosylate derivative was used in the present work because it would be more stable than the benzenesulfonate. Also, the phenoxide ion should be a stronger nucleophilic reagent than ethyl alcohol and this should accord a more $\text{S}_{\text{N}}2$ type reaction involving a smaller possibility for rearrangement.

Dihalocarbenes have been postulated as intermediates in the hydrolysis of haloforms with potassium *t*-butoxide (35,37,38). The intermediate dihalocarbene will add to olefins to give dihalocyclopropane derivatives. After dehalogenation (36) of the dihalocyclopropane compound obtained in this thesis, the product had similar physical properties and an identical infrared spectrum with that obtained by the first synthetic method. The second method was used to prepare a sufficient quantity of cyclopropylcarbinyl phenyl ether for the attempted rearrangement.

The Claisen rearrangement is a thermal reaction. The normal conditions used are temperatures of 200-240°C., with reaction periods of two to five hours. Occasionally a solvent such as diphenyl ether or *N,N*-diethylaniline has been used (33). The rate of rearrangement is not greatly affected by acetic acid or dimethylaniline (39).

Three attempts to cause a Claisen-type rearrangement of cyclopropylcarbinyl phenyl ether were made. The ether was first refluxed (214°C) for six hours and then for 18 hours. In the third attempt the ether was heated in a sealed tube at about 300°C., for ten hours. In all cases the infrared spectrum of the heated material was identical with the starting material and no positive ferric chloride test for phenols was observed.

It thus appears that despite a plausible mechanism, cyclopropylcarbinyl phenyl ether will not undergo a thermal Claisen-type rearrangement, and that in this particular case, the cyclopropane ring is not analogous to the carbon-carbon double bond.

SUMMARY

1. The trifluoroacetates of cyclopropylcarbinol, neopentylglycidylcarbinol and cyclopropylmethylcarbinol were prepared and purified by conventional methods. A rearranged ester which is probably 2-methylcyclohexyl trifluoroacetate was also formed during the synthesis of cyclopropylmethylcarbinyl trifluoroacetate.

2. The rates of solvolysis of these esters were followed conductimetrically in several aqueous ~~solvents~~ solvents at several temperatures. Cyclopropylcarbinyl, neopentylglycidylcarbinyl and 2-methylcyclohexyl trifluoroacetates solvolyzed by acyl-oxygen fission. Thus, cyclopropylcarbinyl trifluoroacetate solvolyzed in methanolic diamine to give methyl trifluoroacetate and cyclopropylcarbinol. Also, 2-methylcyclohexyl trifluoroacetate in methanol gave only methyl trifluoroacetate and 2-methylcyclohexanol. The other ester, cyclopropylmethylcarbinyl trifluoroacetate, solvolyzed via alkyl-oxygen fission, as evidenced by solvolysis in methanol or 50% methanolic diamine to yield cyclopropylmethylcarbinyl methyl ether. The solvolysis appears to proceed with extensive rearrangement as a large percentage of methyl trifluoroacetate (presumably arising from rearranged ester) and 2-methylcyclohexanol were also observed in these solvolyses. The rates, solvent effects and entropies and enthalpies of activation for all of the esters are consistent with the mechanistic postulates (from cleavage) mentioned above.

SUMMARY

1. The trifluoroacetates of cyclopropylcarbinol, nortricycylcarbinol and cyclopropylmethylcarbinol were prepared and purified by conventional methods. A rearranged ester which is probably 2-methylcyclobutyl trifluoroacetate was also formed during the synthesis of cyclopropylmethylcarbonyl trifluoroacetate.

2. The rates of solvolysis of these esters were followed conductimetrically in several aqueous dioxane solvents at several temperatures. Cyclopropylcarbonyl, nortricycylcarbonyl and 2-methylcyclobutyl trifluoroacetates solvolyzed by acyl-oxygen fission. Thus, cyclopropylcarbonyl trifluoroacetate solvolyzed in methanolic dioxane to give methyl trifluoroacetate and cyclopropylcarbinol. Also, 2-methylcyclobutyl trifluoroacetate in methanol gave only methyl trifluoroacetate and 2-methylcyclobutanol. The other ester, cyclopropylmethylcarbonyl trifluoroacetate, solvolyzed via alkyl-oxygen fission, as evidenced by solvolysis in methanol or 50% methanolic dioxane to yield cyclopropylmethylcarbonyl methyl ether. The solvolysis appears to proceed with extensive rearrangement as a large percentage of methyl trifluoroacetate (presumably arising from rearranged ester) and 2-methylcyclobutanol were also observed in these solvolyses. The rates, solvent effects and entropies and enthalpies of activation for all of the esters are consistent with the mechanistic postulates (bond cleavages) mentioned above.

3. Methylnortricyclohexylcarbonyl trifluoroacetate was also prepared but could not be purified. A few kinetic studies on the impure ester indicated that it solvolyzed by alkyl-oxygen fission, and that it was very reactive.

4. Cyclopropylcarbonyl phenyl ether was prepared by two independent methods and its thermal rearrangement was attempted. No rearrangement was observed.

$$k = 2.16 \times 10^{-5} \text{ sec.}^{-1}$$

The data in Tables 41, 42, 43, 44, 45 and 49 were obtained from the solvolysis of the reaction product obtained in the preparation of cyclopropylmethylcarbonyl trifluoroacetate which also contained 2-methylcyclobutyl trifluoroacetate. As 2-methylcyclobutyl trifluoroacetate solvolyzes much slower than the former ester, the latter part of the data (below the solid line in the tables) gave straight lines and the slope of these lines were used to calculate rate constants for this ester in 60% aqueous dioxane.

Cyclopropylmethylcarbinyl trifluoroacetate solvolyzed via allyl-oxygen fission and by rearrangement to 2-methylcyclobutyl trifluoroacetate. This latter ester also solvolyzed under the reaction conditions causing the kinetic plots for the solvolysis of cyclopropylmethylcarbinyl trifluoroacetate to have some curvature towards the end of the reaction. Only that portion of the data that gave the initial straight line (above the solid line in the tables) was used in calculating the reported rate constants.

Methylacryloylacryloyl trifluoroacetate was not obtained pure. The data in Tables 64, 66, 68, 70 and 72 are those obtained directly on the impure ester. The data in Tables 65, 67, 69, 71 and 73 were calculated from the respective original tables using assumed value of R_p (calculated as mentioned in the section "Discussion and Results" of the first part of this thesis). These latter data gave initial straight lines from which the reported solvolysis rate constants for this ester were calculated.
